## MAGNETISATION DYNAMICS

Claire Donnelly

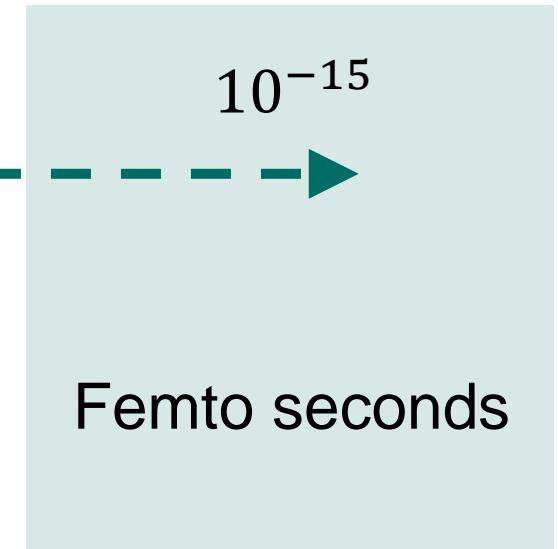

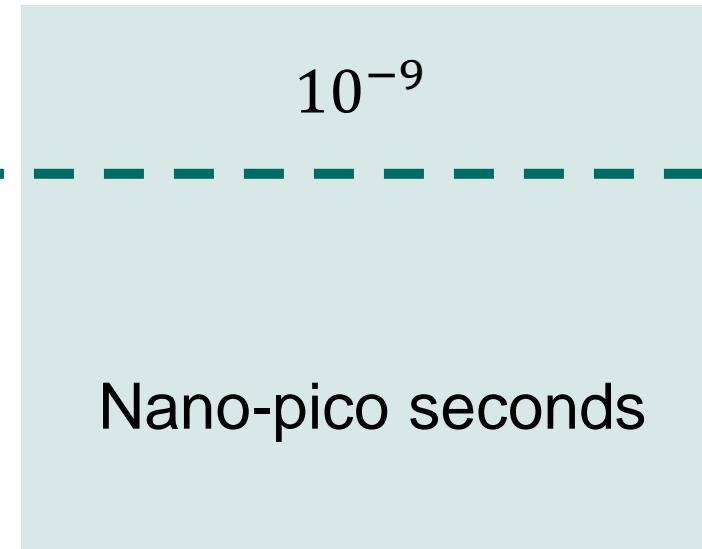

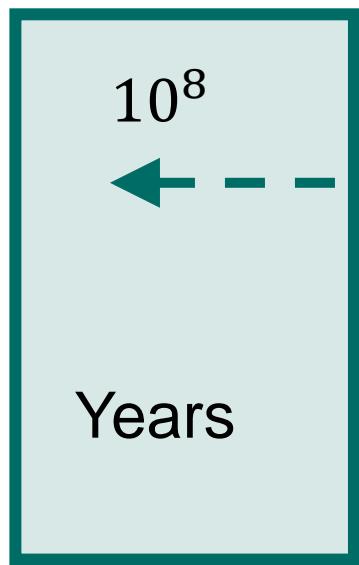

European School of Magnetism 2022

Saarbruecken, 15th September 2022

# DYNAMICS – WHAT TIME SCALES?

Slow!

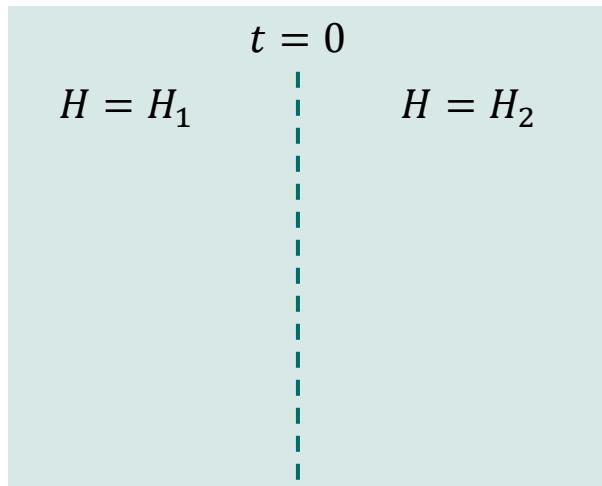

Ultrafast!

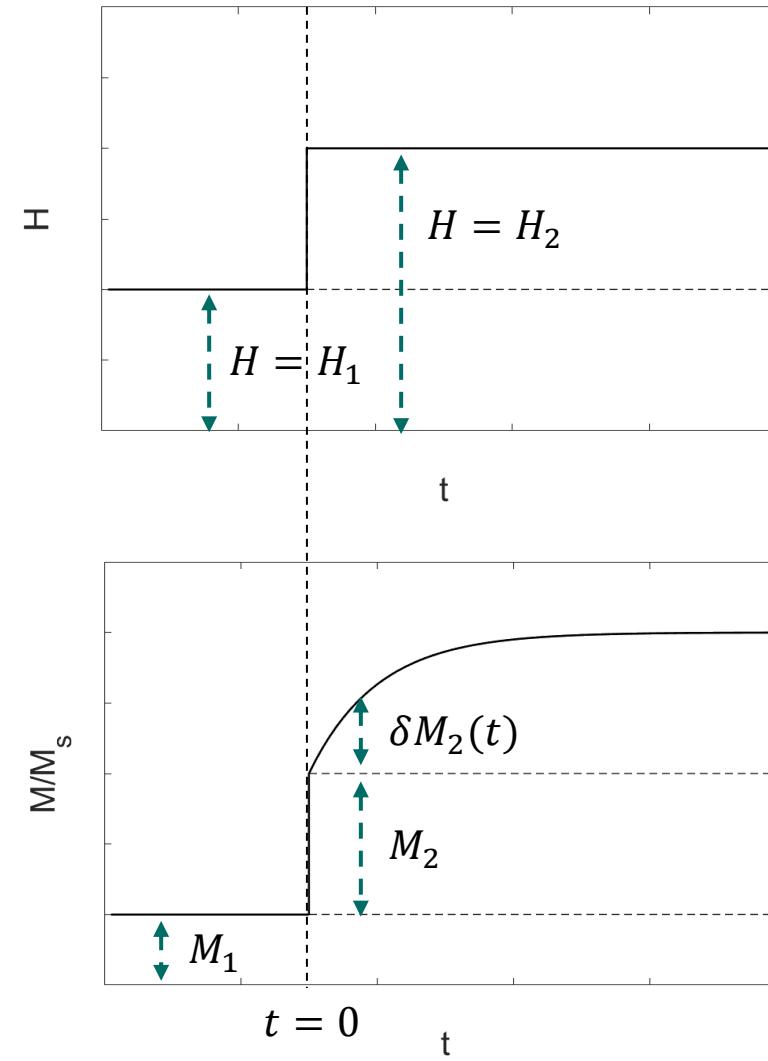

# MAGNETISATION DYNAMICS: VISCOSITY

Imagine an abrupt change in field:

The magnetisation will vary with time:

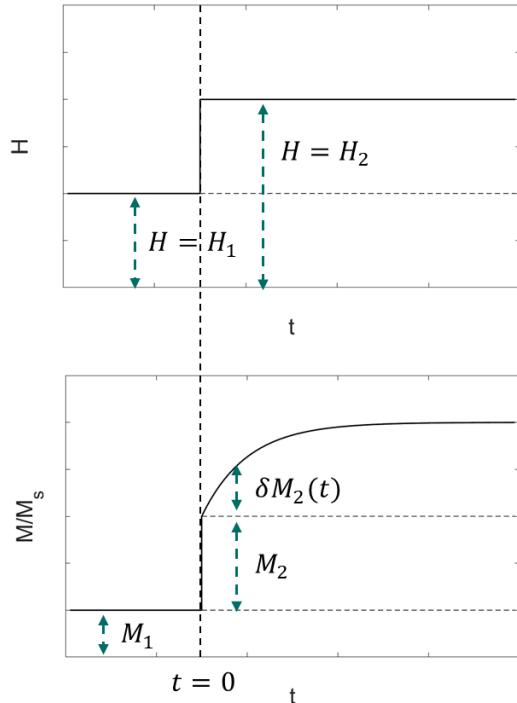

$$I_n(t) = I_{n0}(1 - e^{-t/\tau})$$

# MAGNETISATION DYNAMICS: VISCOSITY

Three main causes of magnetic viscosity:

**Eddy currents**

**Diffusion of impurities – allow domain walls to move**

**Temperature fluctuations**

# EDDY CURRENTS

Changing magnetisation leads  
to “Eddy currents”

Electromagnetic induction:

When a magnetic field changes, an electric field is created:

$$\int E dl = - \int \int \frac{dB}{dt} dS$$

$$2\pi r E(r) = -\mu_0 \pi r^2 \frac{dm}{dt}$$

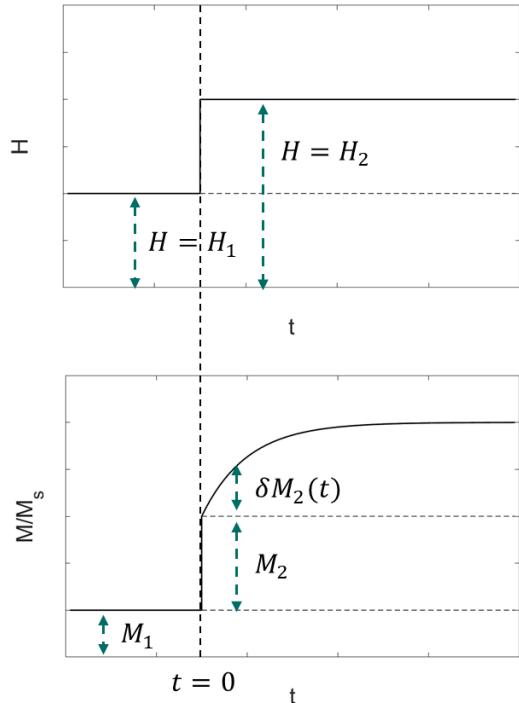

$$E(r) = -\frac{\mu_0 r}{2} \frac{dm}{dt}$$

$$\rightarrow \text{Eddy currents: } i(r) = -\frac{\mu_0 r}{2} \frac{dm}{dt}$$

# MAGNETISATION DYNAMICS: VISCOSITY

Three main causes of magnetic viscosity:

**Eddy currents**

**Diffusion of impurities – allow domain walls to move**

**Temperature fluctuations**

# DIFFUSION OF IMPURITIES

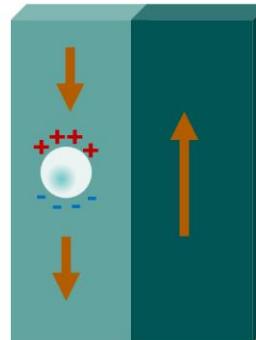

Remember from before:

**Slowly over time, the impurities can adjust themselves**

## DOMAIN WALL PINNING

What causes this pinning?

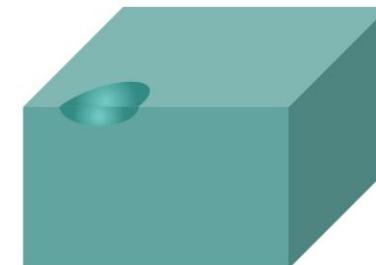

→ Local changes in the energy landscape

Voids

Grain boundaries

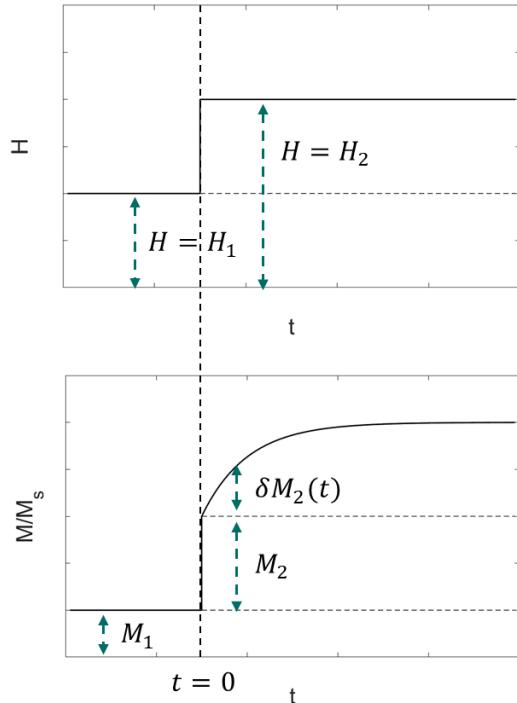

Surface defects

# MAGNETISATION DYNAMICS: VISCOSITY

Three main causes of magnetic viscosity:

**Eddy currents**

**Diffusion of impurities – allow domain walls to move**

**Temperature fluctuations**

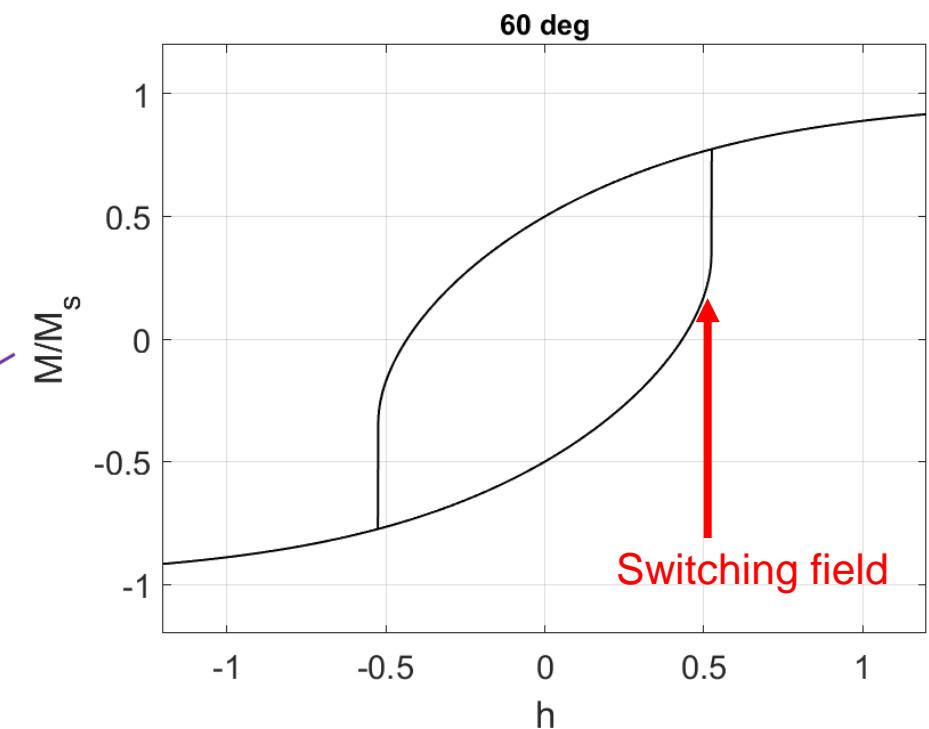

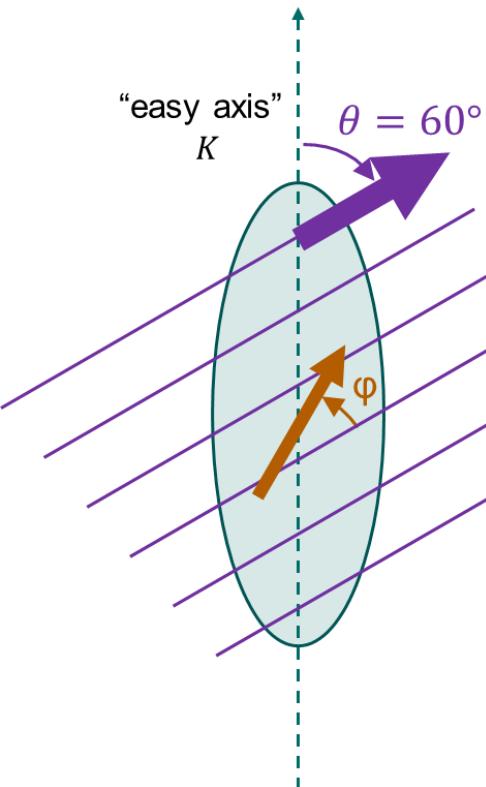

# THERMAL FLUCTUATIONS: REVISITING STONER WOHLFAHRT

Reversal of single domain particle:

$$E = K \sin^2(\theta - \varphi) - \mu_0 H M_S K \cos \varphi$$

Anisotropy      vs      Magnetic field

**Zero-temperature model!**

# THERMAL FLUCTUATIONS: REVISITING STONER WOHLFAHRT

In reality, we have finite temperature

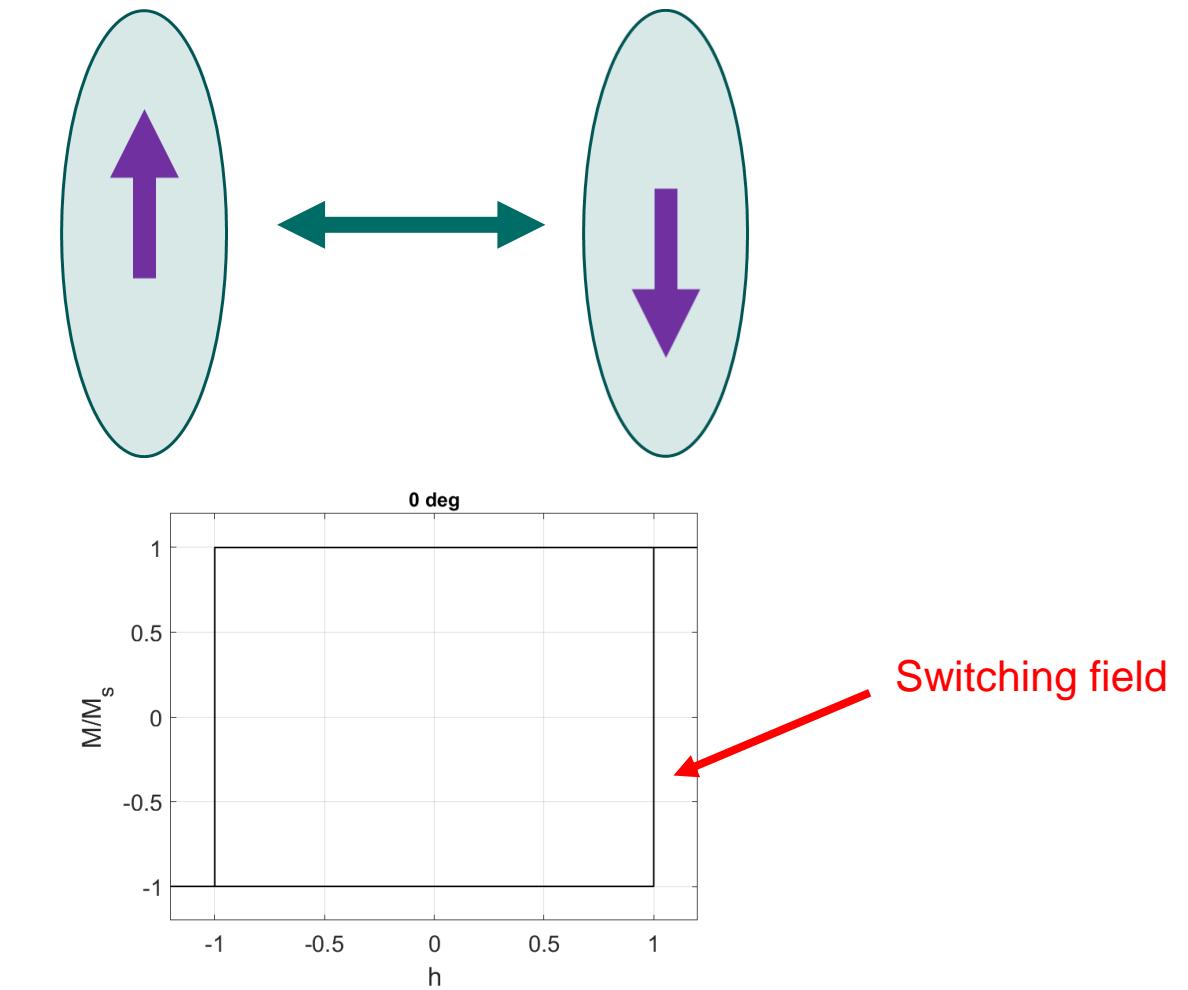

What is our energy barrier?

Rotate through the “hard axis”  $\theta = 90^\circ$ :

$$E = v(K \sin^2(\theta - \varphi) - \mu_0 H M_S \cos \varphi)$$

Anisotropy      vs      Magnetic field

Zero field energy barrier  $\rightarrow \Delta E \sim K v$

# THERMAL FLUCTUATIONS: REVISITING STONER WOHLFAHRT

In reality, we have finite temperature

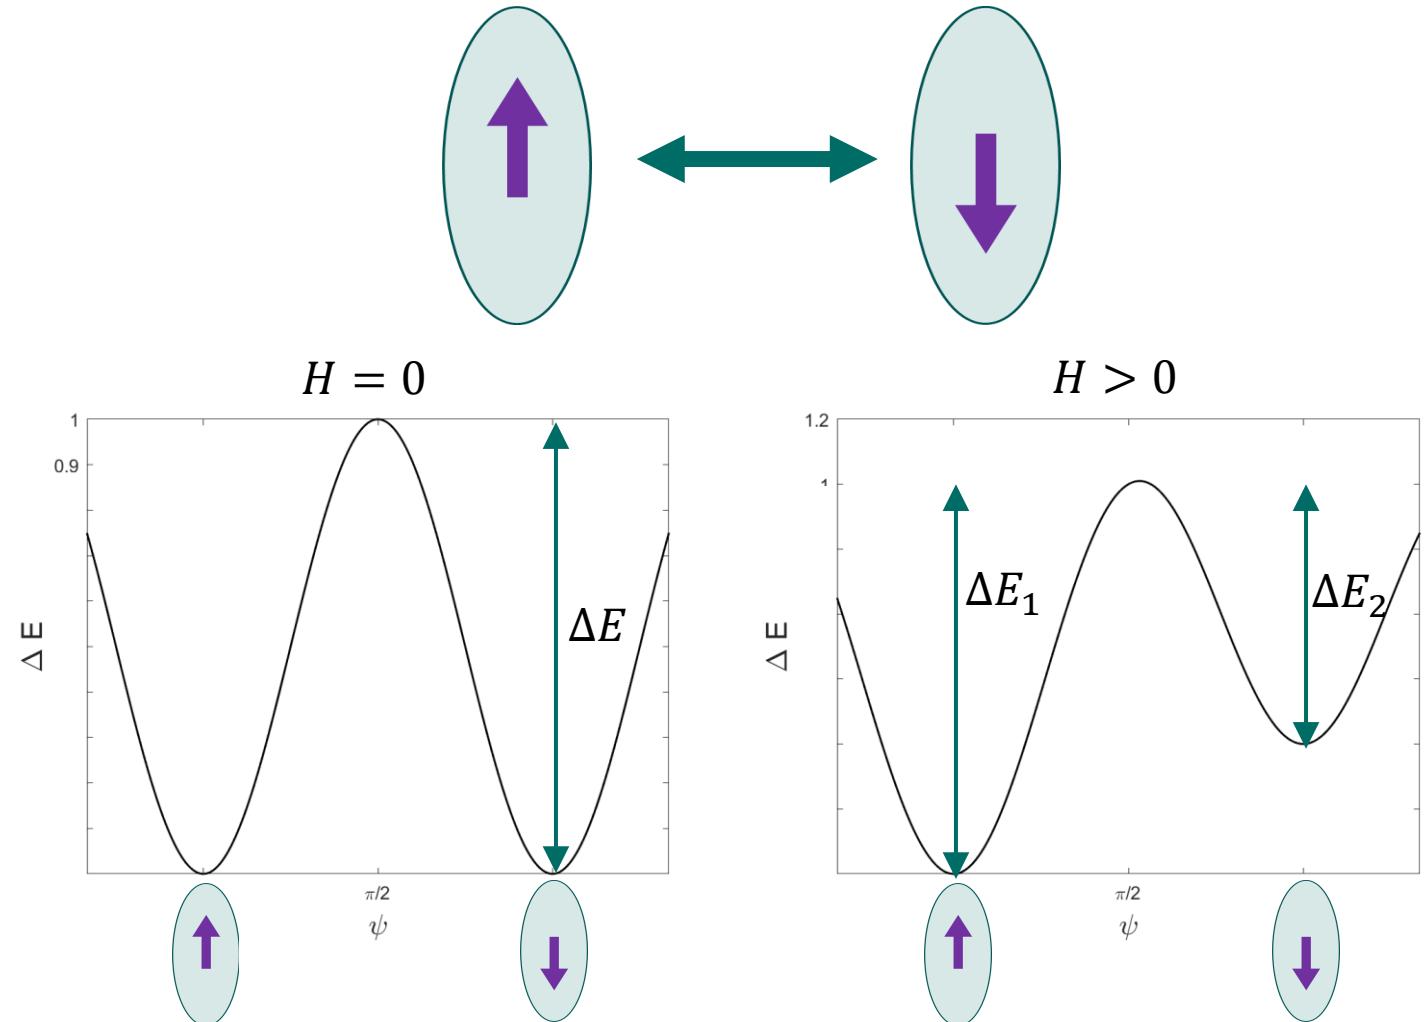

What is our energy barrier?

Rotate through the “hard axis”  $\theta = 90^\circ$ :

$$E = v(K \sin^2(\theta - \varphi) - \mu_0 H M_S \cos \varphi)$$

Anisotropy      vs      Magnetic field

Plot energy as a function of angle:

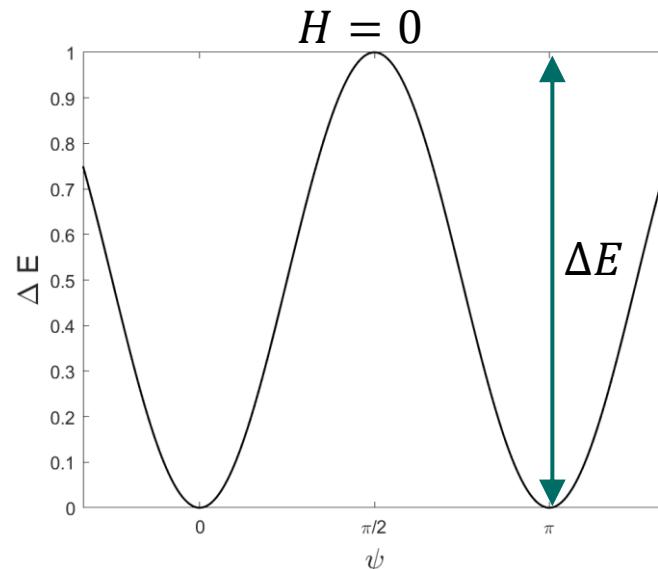

# THERMAL FLUCTUATIONS: REVISITING STONER WOHLFAHRT

In reality, we have finite temperature

$$E = v(K \sin^2(\theta - \varphi) - \mu_0 H M_S \cos \varphi)$$

Anisotropy      vs      Magnetic field

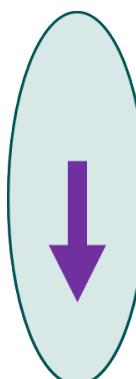

Energy barrier →  $\Delta E = vK$

Thermal activation →  $E_{th} = \frac{k_B T}{2}$

For a **small enough** particle,  
we can get spontaneous switching!  
 $T = 273\text{K} \rightarrow k_B T = 3.77 \times 10^{-21} \text{J}$   
 $K \sim 10^5 \frac{\text{J}}{\text{m}^3}$  for Co  
 $v = 1.9 \times 10^{-26} \text{m}^3$  so  $d = 1.7 \times 10^{-9} \text{m}$

Volume

“superparamagnetism”

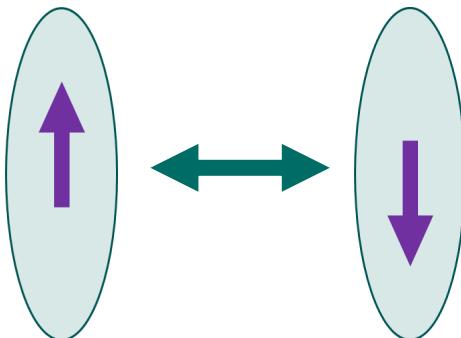

# SUPERPARAMAGNETISM: TIME SCALES

What is the time scale of the oscillations?

i.e. time between two fluctuations?

Relaxation time ~ **Attempt frequency** and **Boltzmann probability**

$$\tau_0 \quad e^{\Delta/k_B T}$$

$$\sim 10^{-9} - 10^{-10} \text{ s}$$

Spin-flip / Neel relaxation time:  $\tau_N = \tau_0 e^{\Delta/k_B T}$

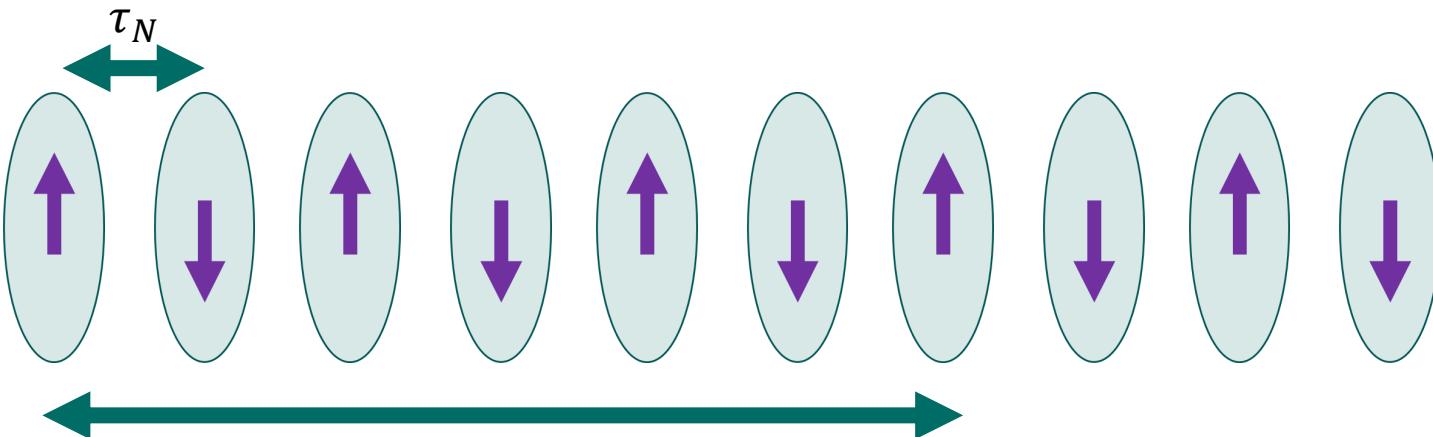

Can range from nanoseconds to years!

# SUPERPARAMAGNETISM: BLOCKING TEMPERATURE

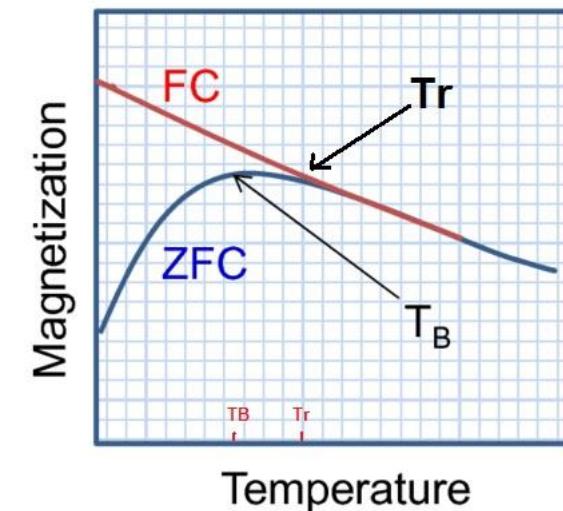

Imagine a superparamagnetic particle is measured over time  $\tau_M$

If  $\tau_M \gg \tau_N$  then you measure zero!

◆  
 $\tau_M < \tau_N$   
 $\langle m \rangle \rightarrow m$

Magnet “blocked” in its initial state

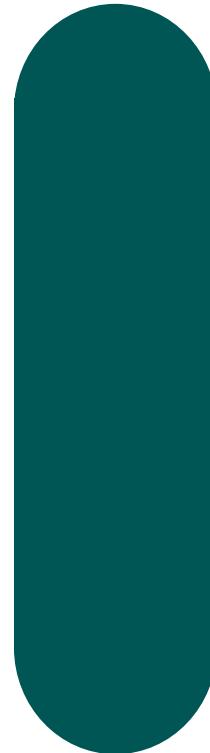

- FC : Field-cooled
- ZFC: Zero field-cooled
- T<sub>B</sub> : Blocking temperature
- Tr : Irreversible point temperature

# SUPERPARAMAGNETISM – OF NANOSTRUCTURES

Not only intrinsic anisotropy: can have fluctuations in small nanoislands:

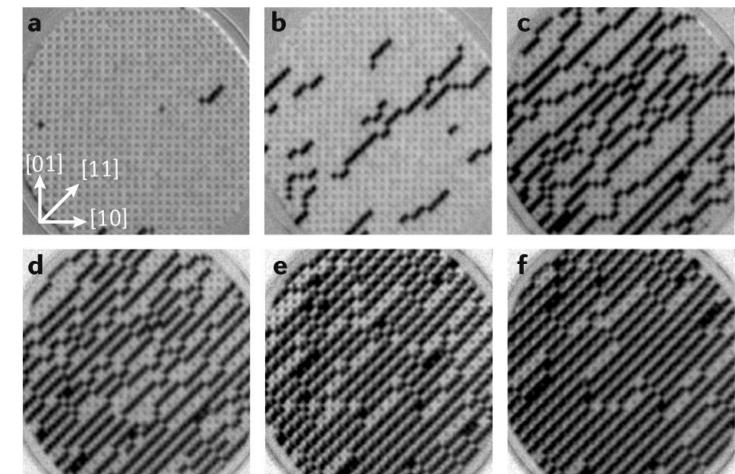

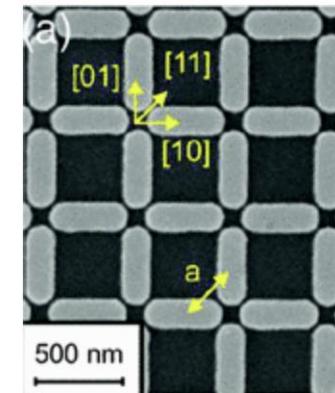

For patterned nanostructures  
(shape anisotropy)

Blocking temperature: temperature at which the structures become thermally active.

Can tune with shape!

Artificial Spin ice

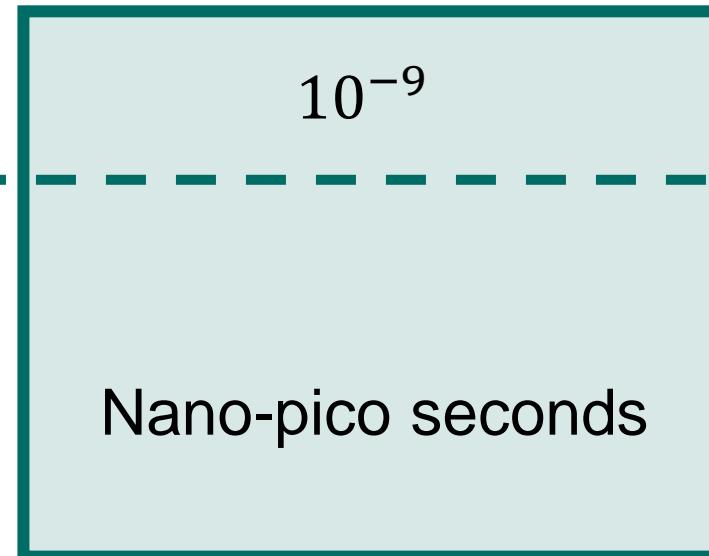

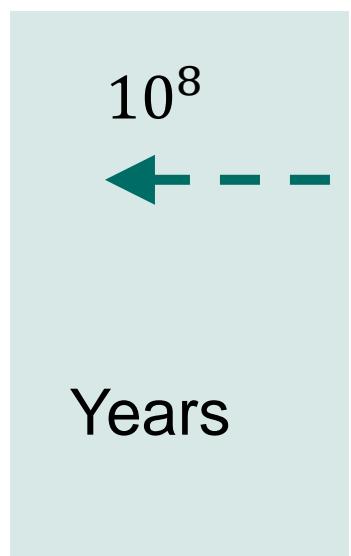

Farhan et al. Phys. Rev. Lett. 111, 057204 (2013).

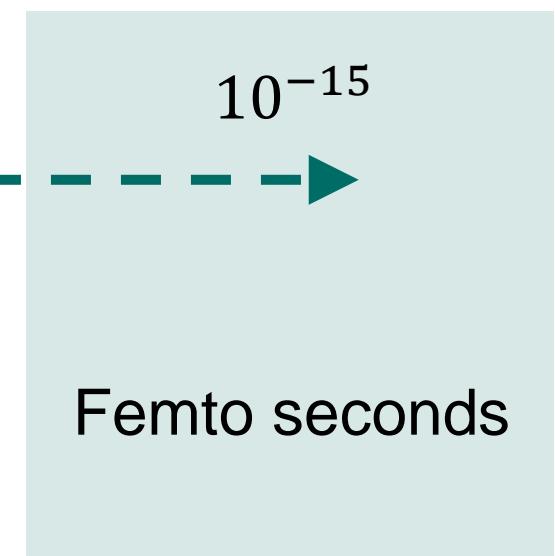

# DYNAMICS – WHAT TIME SCALES?

Slow!

GHz - THz

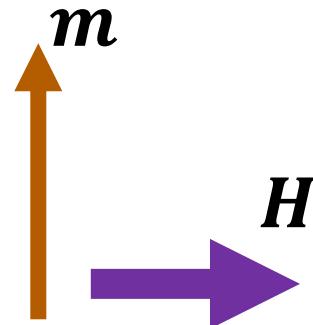

Ultrafast!

## FAST SPIN DYNAMICS:

Fast response of magnetisation to an excitation?

Let's think about how the magnetisation reacts to a magnetic field:

What does the magnetic field apply?

The field applies a torque:  $M \times H$

Because the magnetic moment has angular momentum

# CONSIDER THE GYROMAGNETIC RATIO

What is the gyromagnetic ratio?

$$\frac{1}{\gamma} \frac{dM}{dt} = -M \times H$$

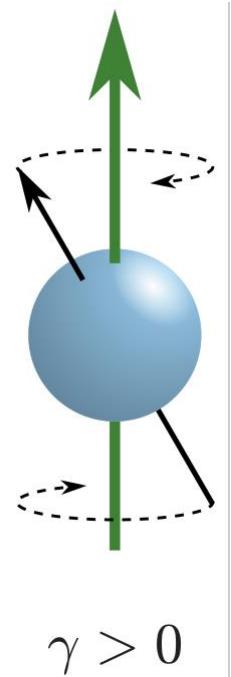

Ratio of magnetic moment to angular momentum  $\gamma = \frac{\mu}{L}$

It determines the precession of the magnetisation based on an applied field

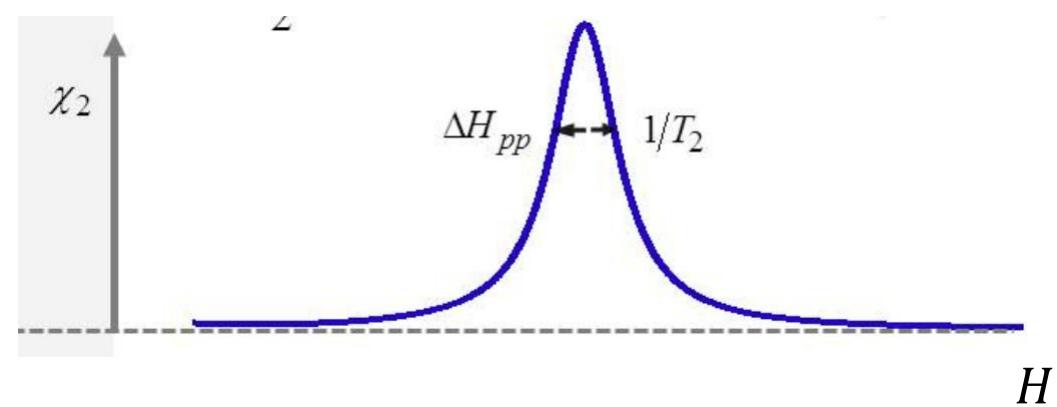

# FERROMAGNETIC RESONANCE

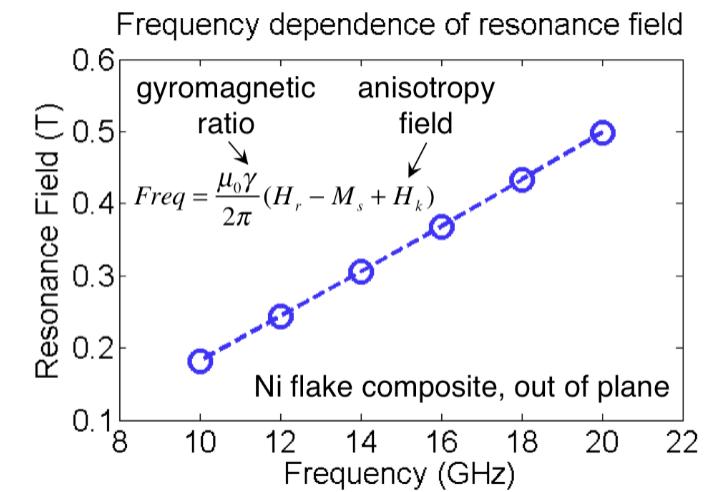

Ferromagnetic body under applied field strongly absorbs certain frequencies of field:

$$\omega = 2\pi f = \gamma B$$

$\gamma$  = gyromagnetic ratio

# BLOCH EQUATION

*Effective field: includes all contributions!*

$$\frac{d\mathbf{M}}{dt} = -\gamma \mathbf{M} \times \mathbf{H}_{eff}$$

Angle to the field: constant!

Precesses with angular velocity  $\omega = \gamma |\mathbf{B}|$

$\sim 28 \text{ GHz/T}$

# LANDAU LIFSHITZ GILBERT EQUATION

But! We see from Hysteresis loops that in the end, a magnetic field can saturate a sample

- Energy dissipation (or damping)
- → energy transferred to lattice vibrations, spin waves, & heating of conduction electrons
- Include damping into effective field:

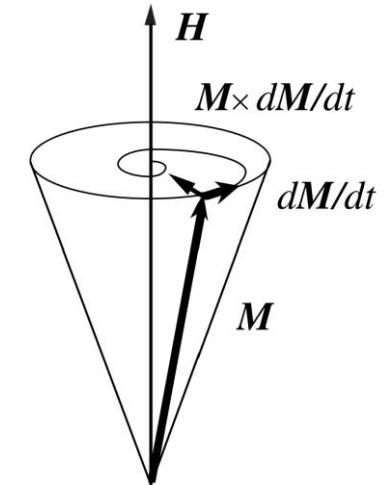

$$\frac{d\mathbf{M}}{dt} = -\gamma \mathbf{M} \times \mathbf{H}_{eff} - \lambda \mathbf{M} \times (\mathbf{M} \times \mathbf{H}_{eff})$$

Which was rewritten as: (by Gilbert)

$$\frac{d\mathbf{M}}{dt} = -\gamma \mathbf{M} \times \mathbf{H}_{eff} - \frac{\alpha}{M_S} \lambda \mathbf{M} \times \frac{d\mathbf{M}}{dt}$$

$\alpha = \frac{\lambda M_S}{\gamma}$

**→ Gilbert damping factor**

# LANDAU LIFSHITZ EQUATION

$$\frac{d\mathbf{M}}{dt} = -\gamma \mathbf{M} \times \mathbf{H}_{eff} - \frac{\alpha}{M_S} \lambda \mathbf{M} \times \frac{d\mathbf{M}}{dt}$$

**What is alpha?**

Determines the damping of a material

→ Affects the dynamics

Low damping materials:

CoFeB, Py, YIG

Depends on intrinsic and extrinsic effects

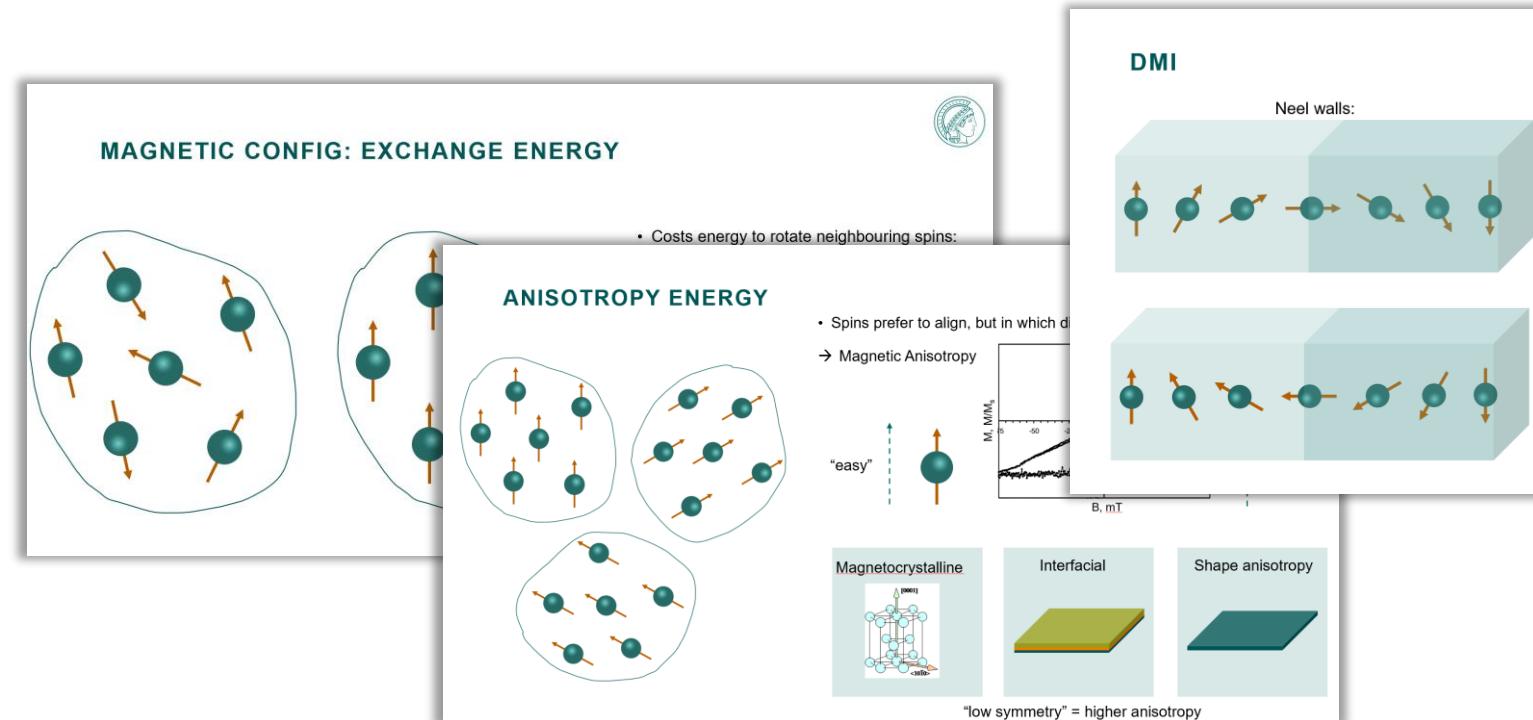

# LANDAU LIFSHITZ EQUATION

$$\frac{d\mathbf{M}}{dt} = -\gamma \mathbf{M} \times \mathbf{H}_{eff} - \frac{\alpha}{M_S} \lambda \mathbf{M} \times \frac{d\mathbf{M}}{dt}$$

What is this effective field?

Composed of different contributions

Including magnetic field!

## Interactions of spins – what happens in multi-spin systems?

# GYROMAGNETIC RATIO & APPLICATIONS

Could you talk about the gyromagnetic ratio in terms of applications?

$$\frac{d\mathbf{M}}{dt} = -\gamma \mathbf{M} \times \mathbf{H}_{eff} - \frac{\alpha}{M_S} \lambda \mathbf{M} \times \frac{d\mathbf{M}}{dt}$$

→ Typically, damping parameter optimised instead!

Ratio of magnetic moment to angular momentum

$$\gamma = \frac{\mu}{L} \quad \sim 28 \text{ GHz/T}$$

- Magnetism is fast!
- However, not so easy to tailor...

# MICROMAGNETICS WITH THE LLG

## Micromagnetic simulations

Minimise energy or

Solve the LLG equation

Very robust for micromagnetic problems

# SPIN EXCITATIONS

**Now we know how the magnetisation reacts to the magnetic field**

**We had ferromagnetic resonance: spins precess in phase...**

**What happens when we think about an excitation of the spin**

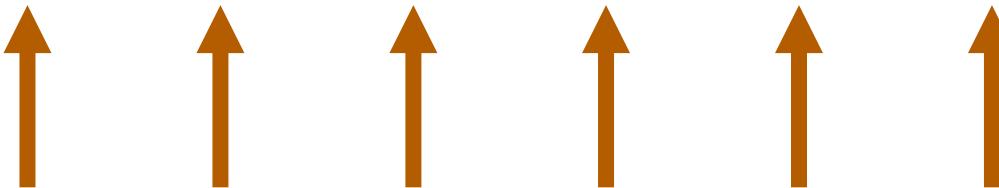

We have the ground state:

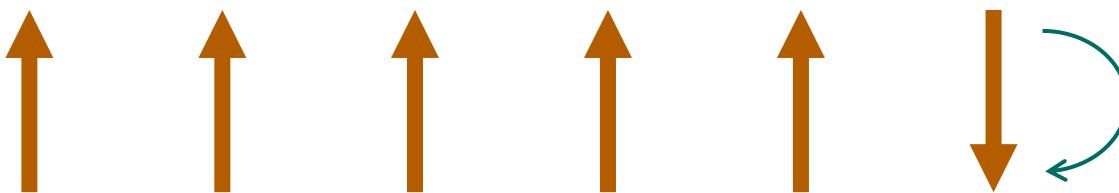

# SPIN EXCITATIONS

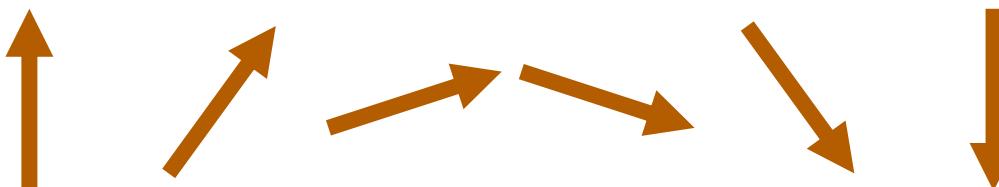

We have the ground state:

What is the smallest excitation of this ground state?

Can distribute over many spins:

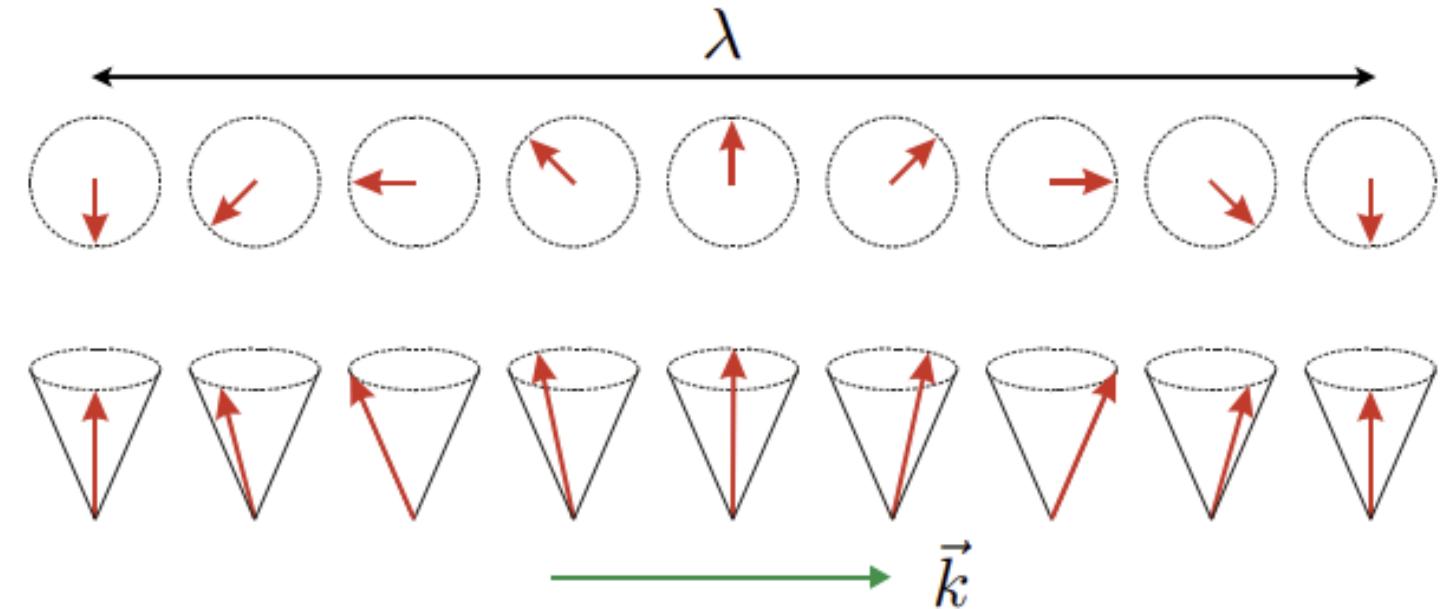

# SPIN WAVES

What this leads to:

Spins all precessing at the same frequency

But: out of phase with one another:

→ Propagating spin waves

# PROPERTIES OF SPIN WAVES

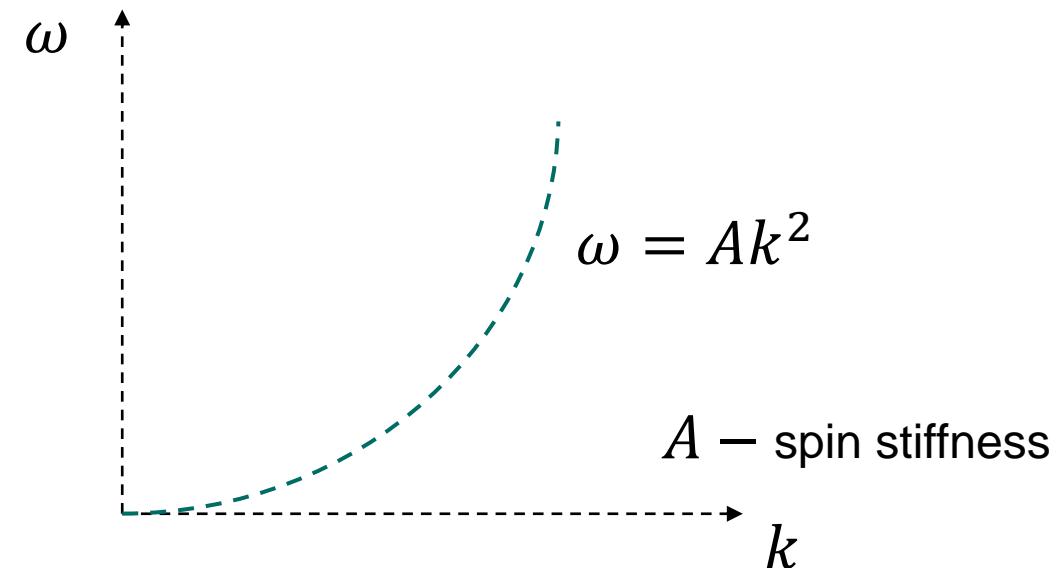

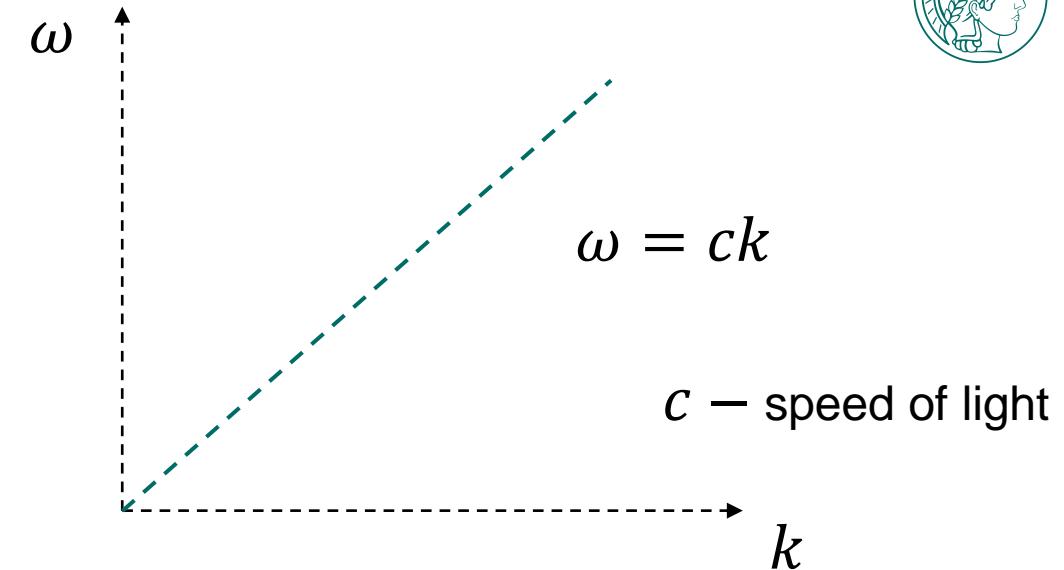

Let's think about "normal" waves

Take light as an example. What defines light?

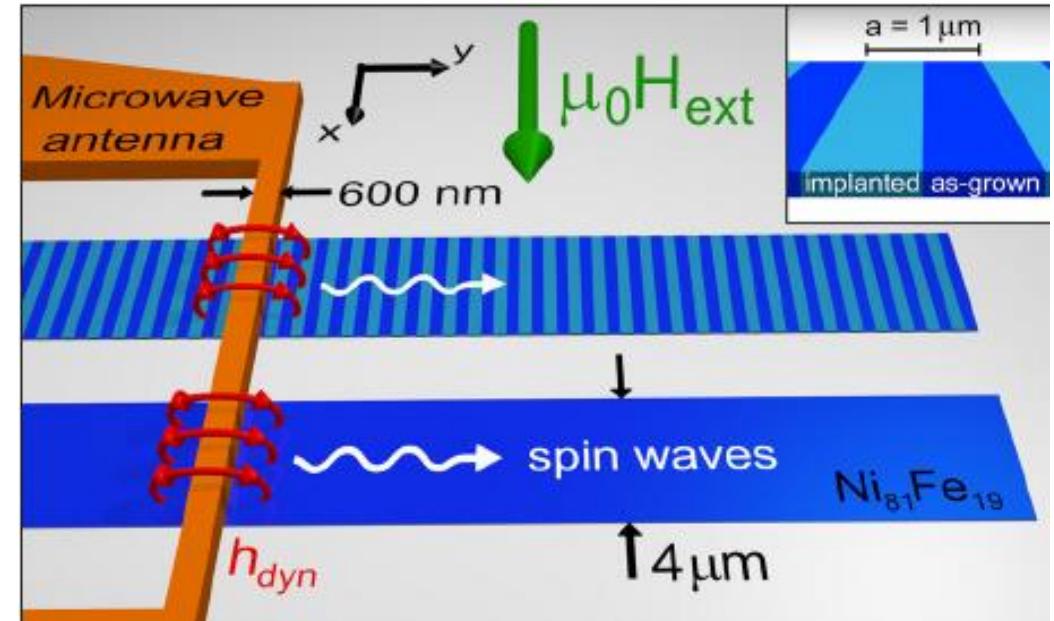

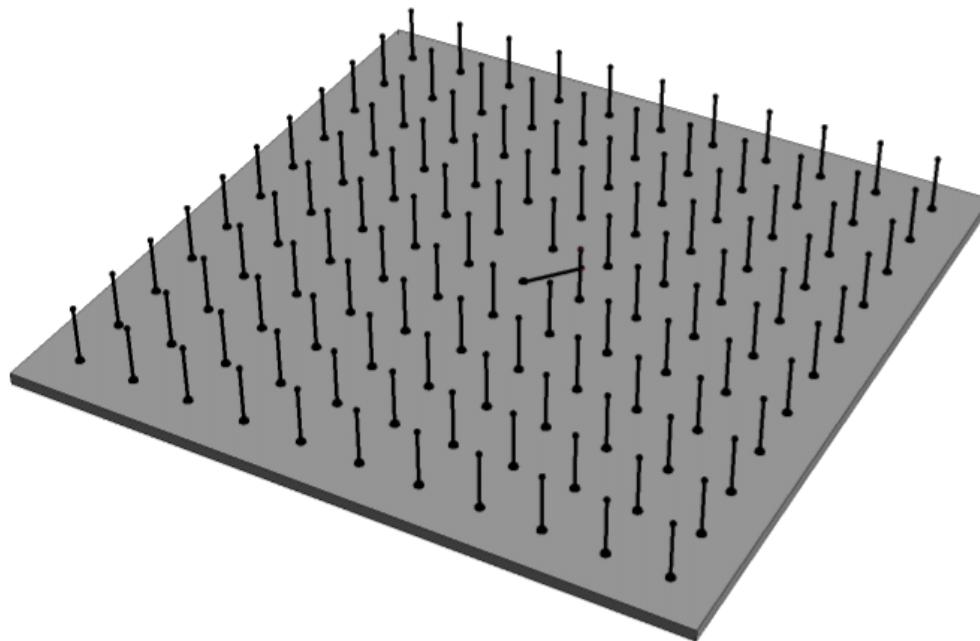

Frequency, wavelength  $\rightarrow$  dispersion relation

Quanta: the equivalent of a photon?

Magnons always present at finite temp

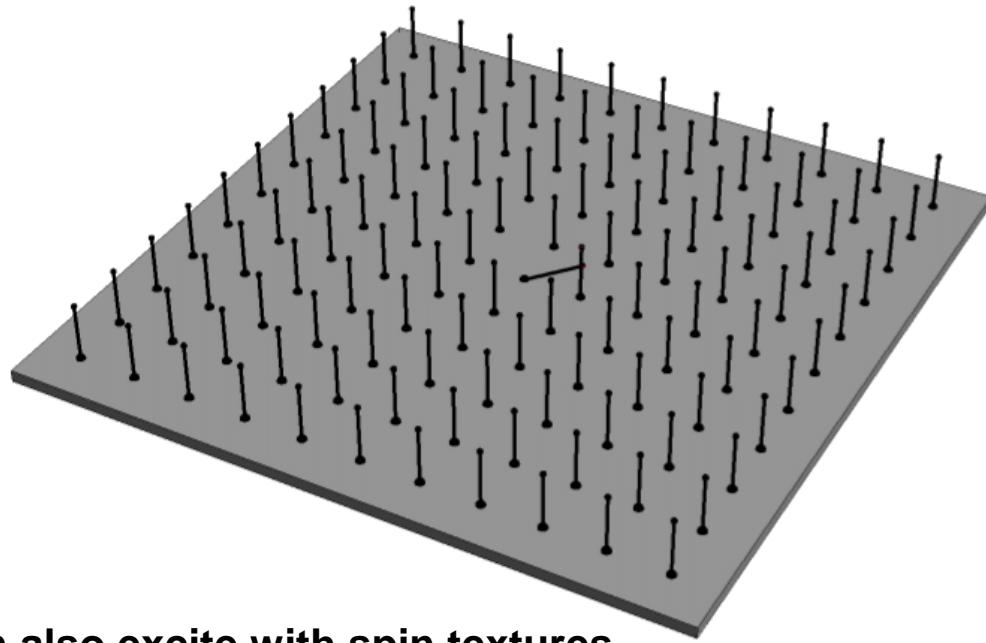

# PROPERTIES OF SPIN WAVES

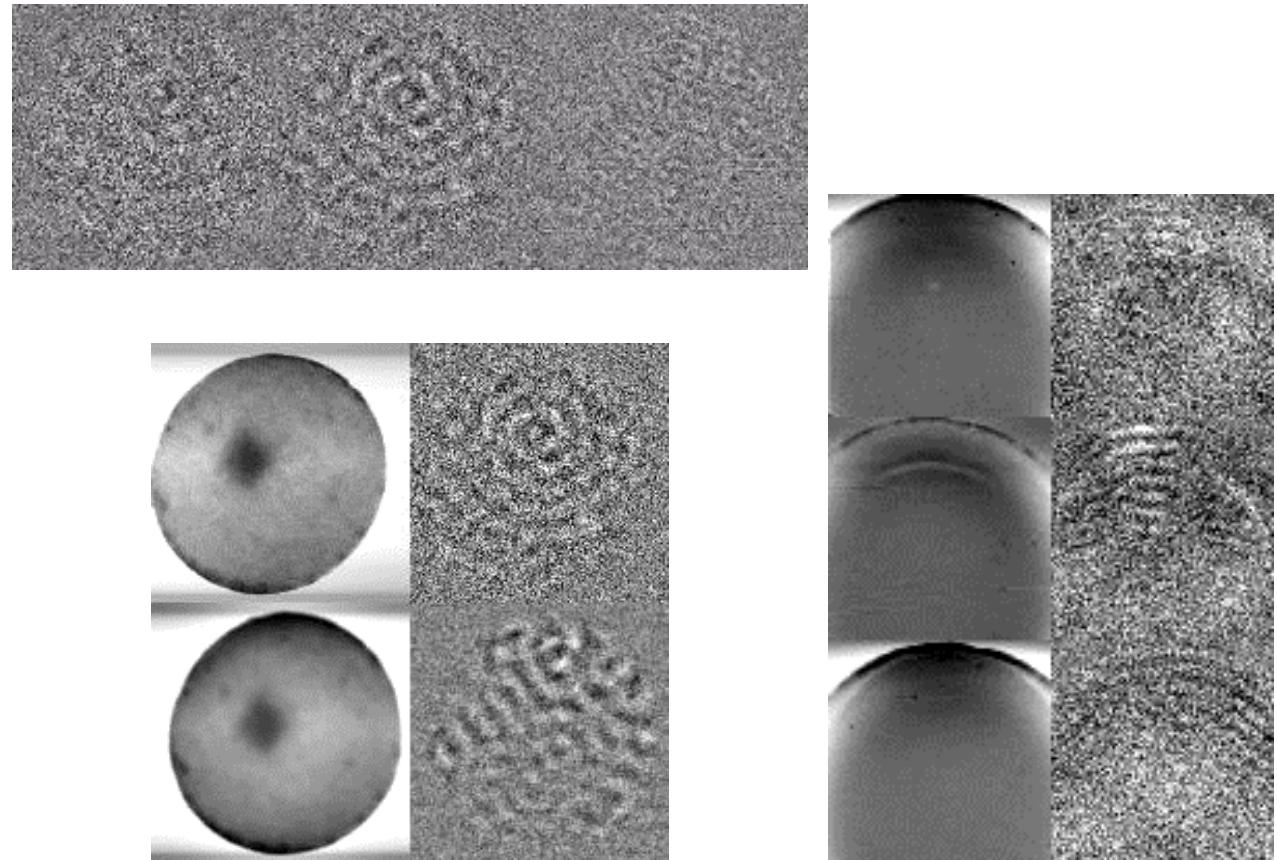

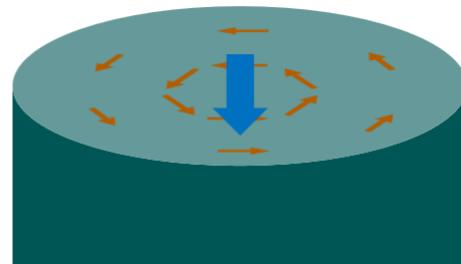

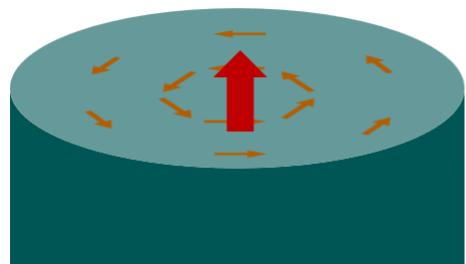

Excite spin waves with an antenna

# PROPERTIES OF SPIN WAVES

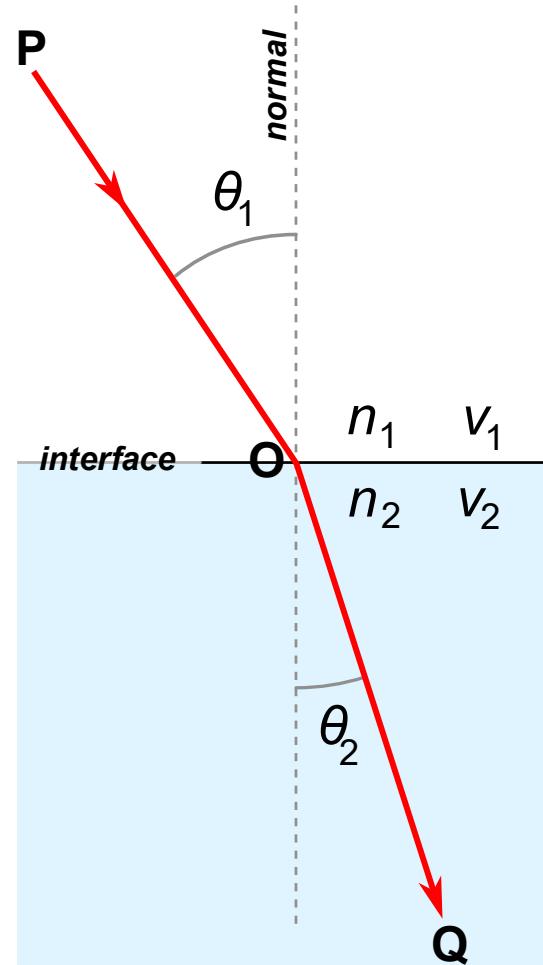

**Can also excite with spin textures**

→ nanoscale, ideal for spin wave excitation

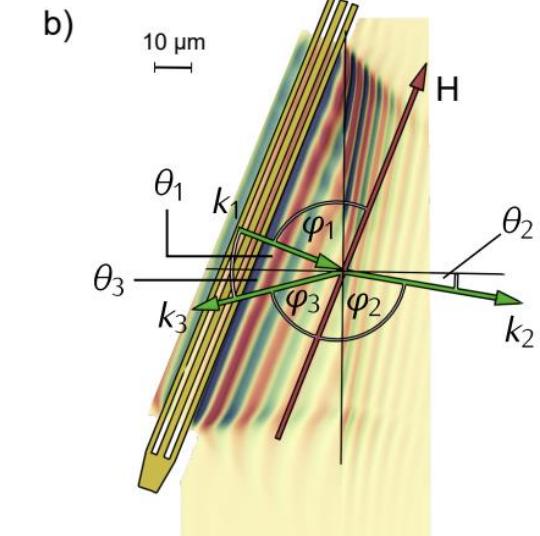

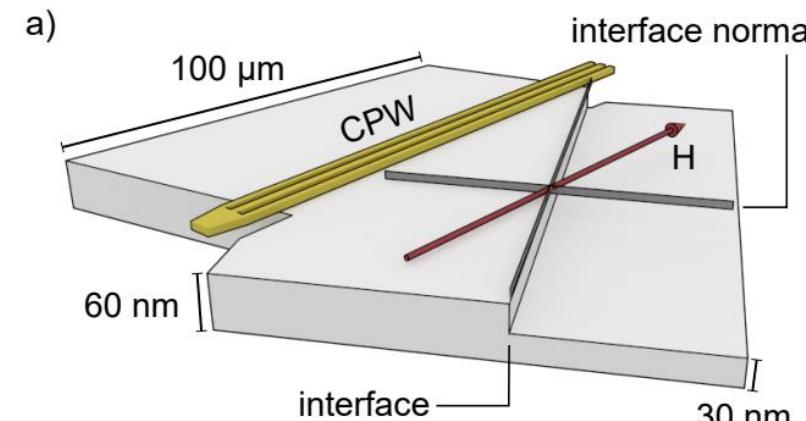

Mayr et al., *Nano Lett.* 2021, 21, 4 (2021)

# PROPERTIES OF SPIN WAVES

In light, different materials have different refractive indices.

**Snell's law** In magnetic materials

Stigloher et al., Phys. Rev. Lett. 117, 037204 (2016)

## Optically Inspired Nanomagnonics with Nonreciprocal Spin Waves in Synthetic Antiferromagnets

Edoardo Albisetti,\* Silvia Tacchi, Raffaele Silvani, Giuseppe Scaramuzzi, Simone Finizio, Sebastian Wintz, Christian Rinaldi, Matteo Cantoni, Jörg Raabe, Giovanni Carlotti, Riccardo Bertacco, Elisa Riedo,\* and Daniela Petti\*

**Spin wave lenses:** domain wall used to excite spin waves

**Pattern domain wall – define different waves**

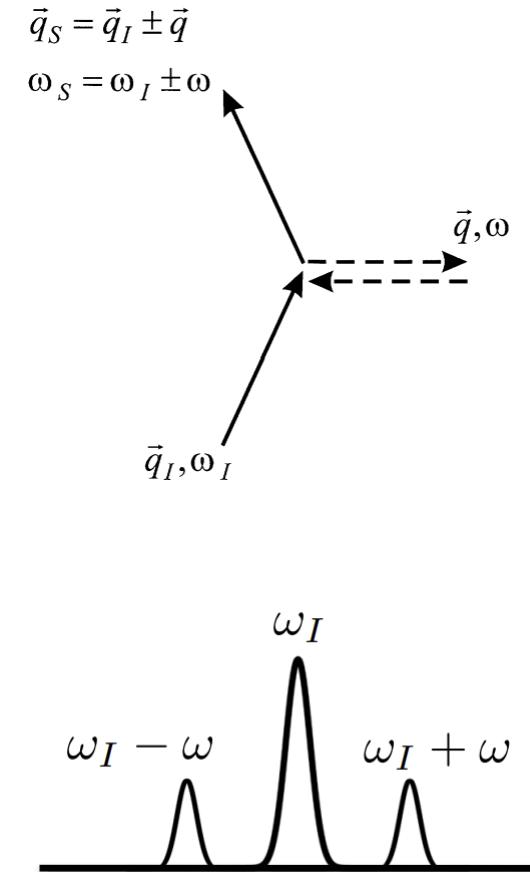

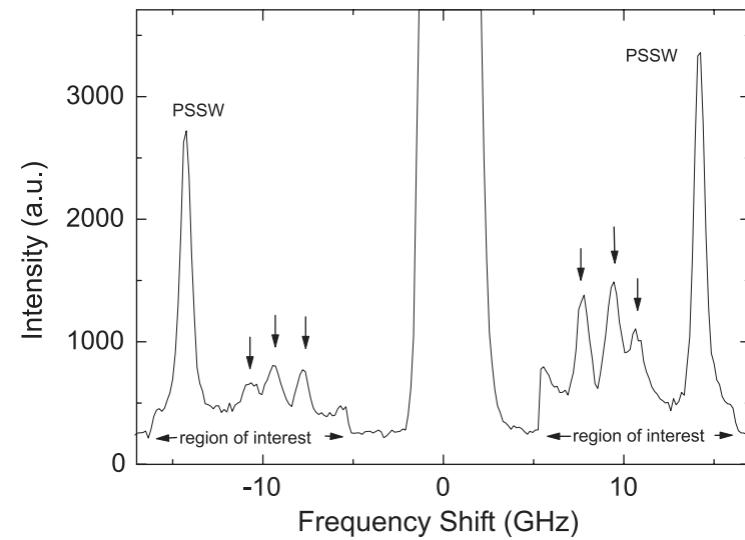

# MEASURING SPIN WAVES

## Brillouin Scattering

Scatter photons from surface spin waves of films

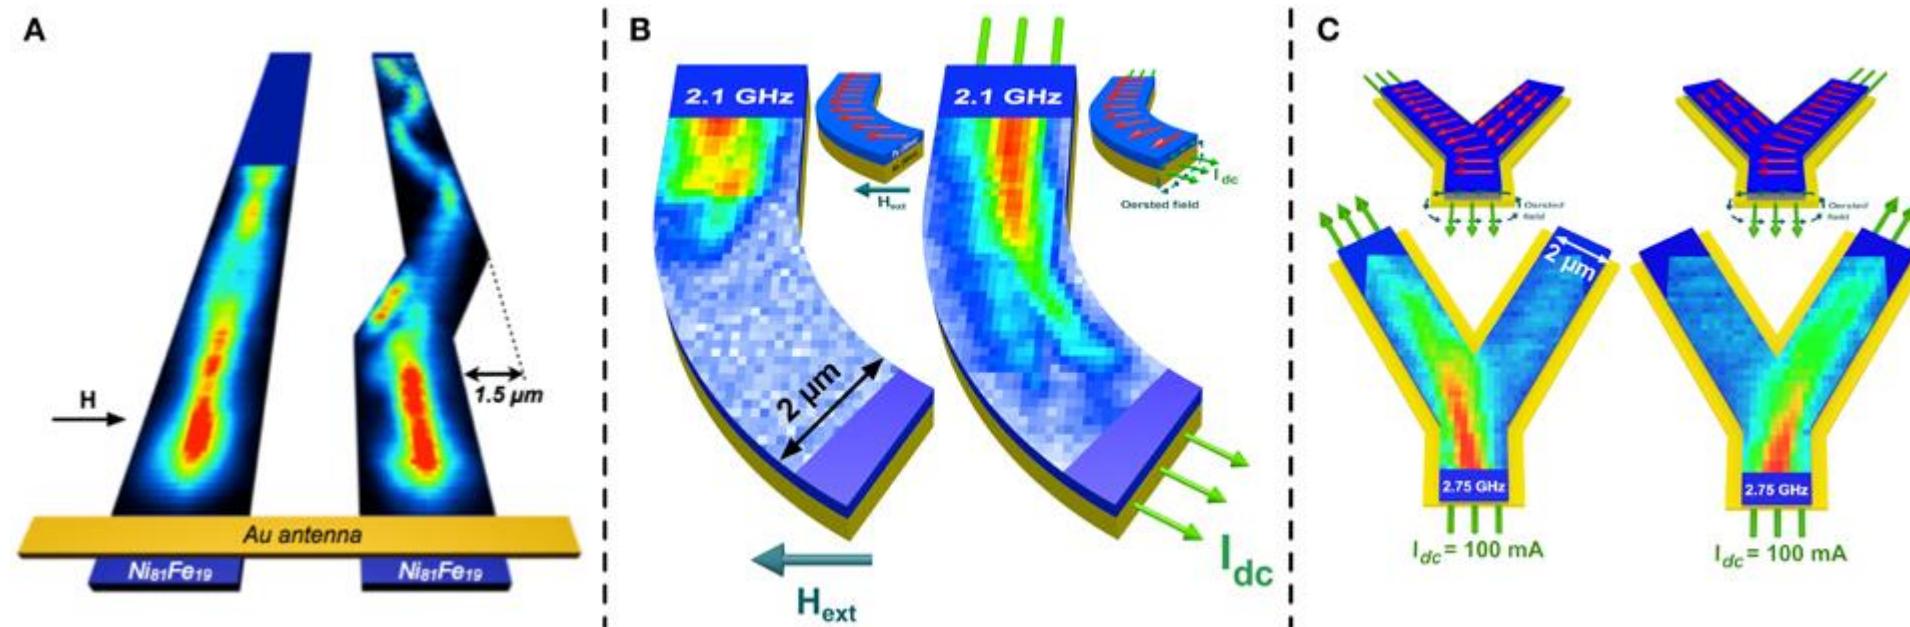

Reflected photons give information on spin waves that are created (Stokes) or annihilated (anti-Stokes)

# MEASURING SPIN WAVES

Brillouin Scattering – microfocused!

Not limited to coherent spin waves!

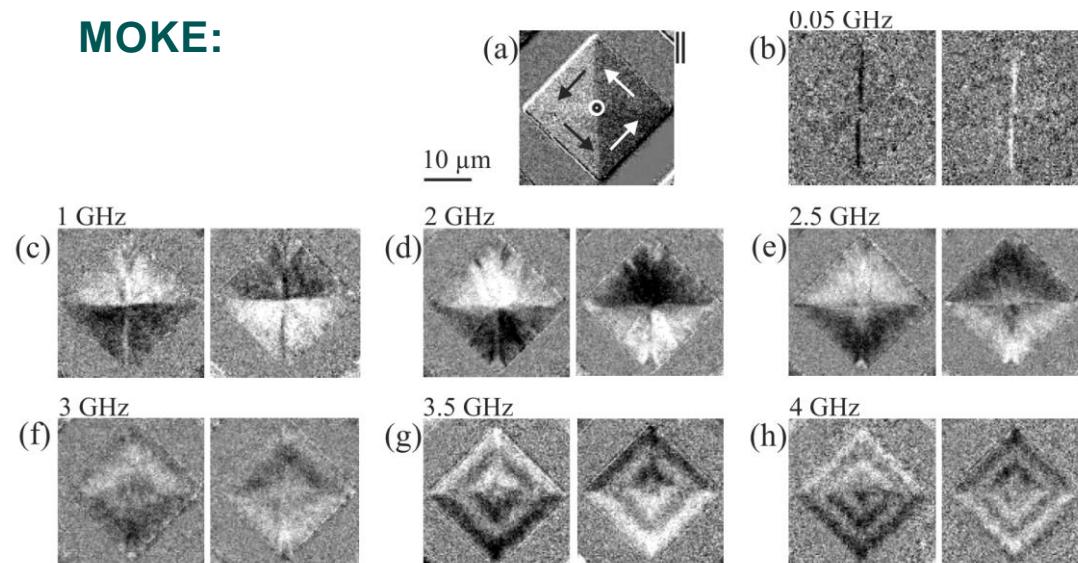

Sebastian et al., <https://doi.org/10.3389/fphy.2015.00035>

# MEASURING SPIN WAVES

Or apply pump-probe techniques to measure *coherent spin waves*:

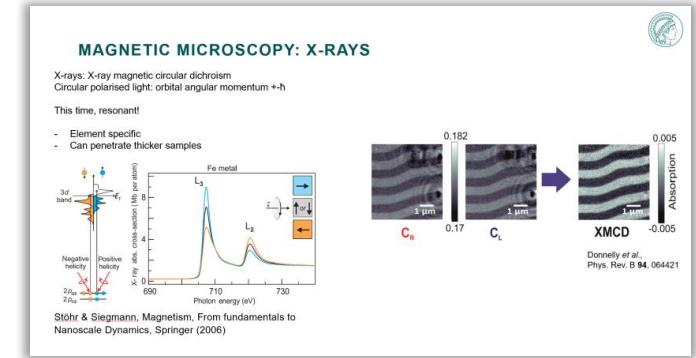

## MOKE:

## Time resolved MOKE

- Pump probe rotation of linear polarised light
- ps temporal resolution, 100s nm - μm spatial resolution

## X-ray microscopy

Albisetti et al., *Adv. Mat.* 32, 1906439 (2020)

## Synchrotron X-rays

- Time resolved Scanning transmission X-ray microscopy
- Pump-probe XMCD
- Ps temporal resolution, nm spatial resolution

# MEASURING MAGNETISATION DYNAMICS – FASTER?

# MEASURING MAGNETISATION DYNAMICS – FASTER?

Free electron laser

Very long accelerator: European XFEL 3.4 km long!

Ultra-bright, ultra-short X-ray pulses

$10^{12}$  photons/s

~fs pulse length

- Sub-100 nm wavelength magnons
- Manipulation on the nanoscale
- Creation of sub-micrometre devices

“magnonics offers lower energy consumption, easier integrability and compatibility with CMOS structure”

## OTHER TYPES OF DYNAMICS:

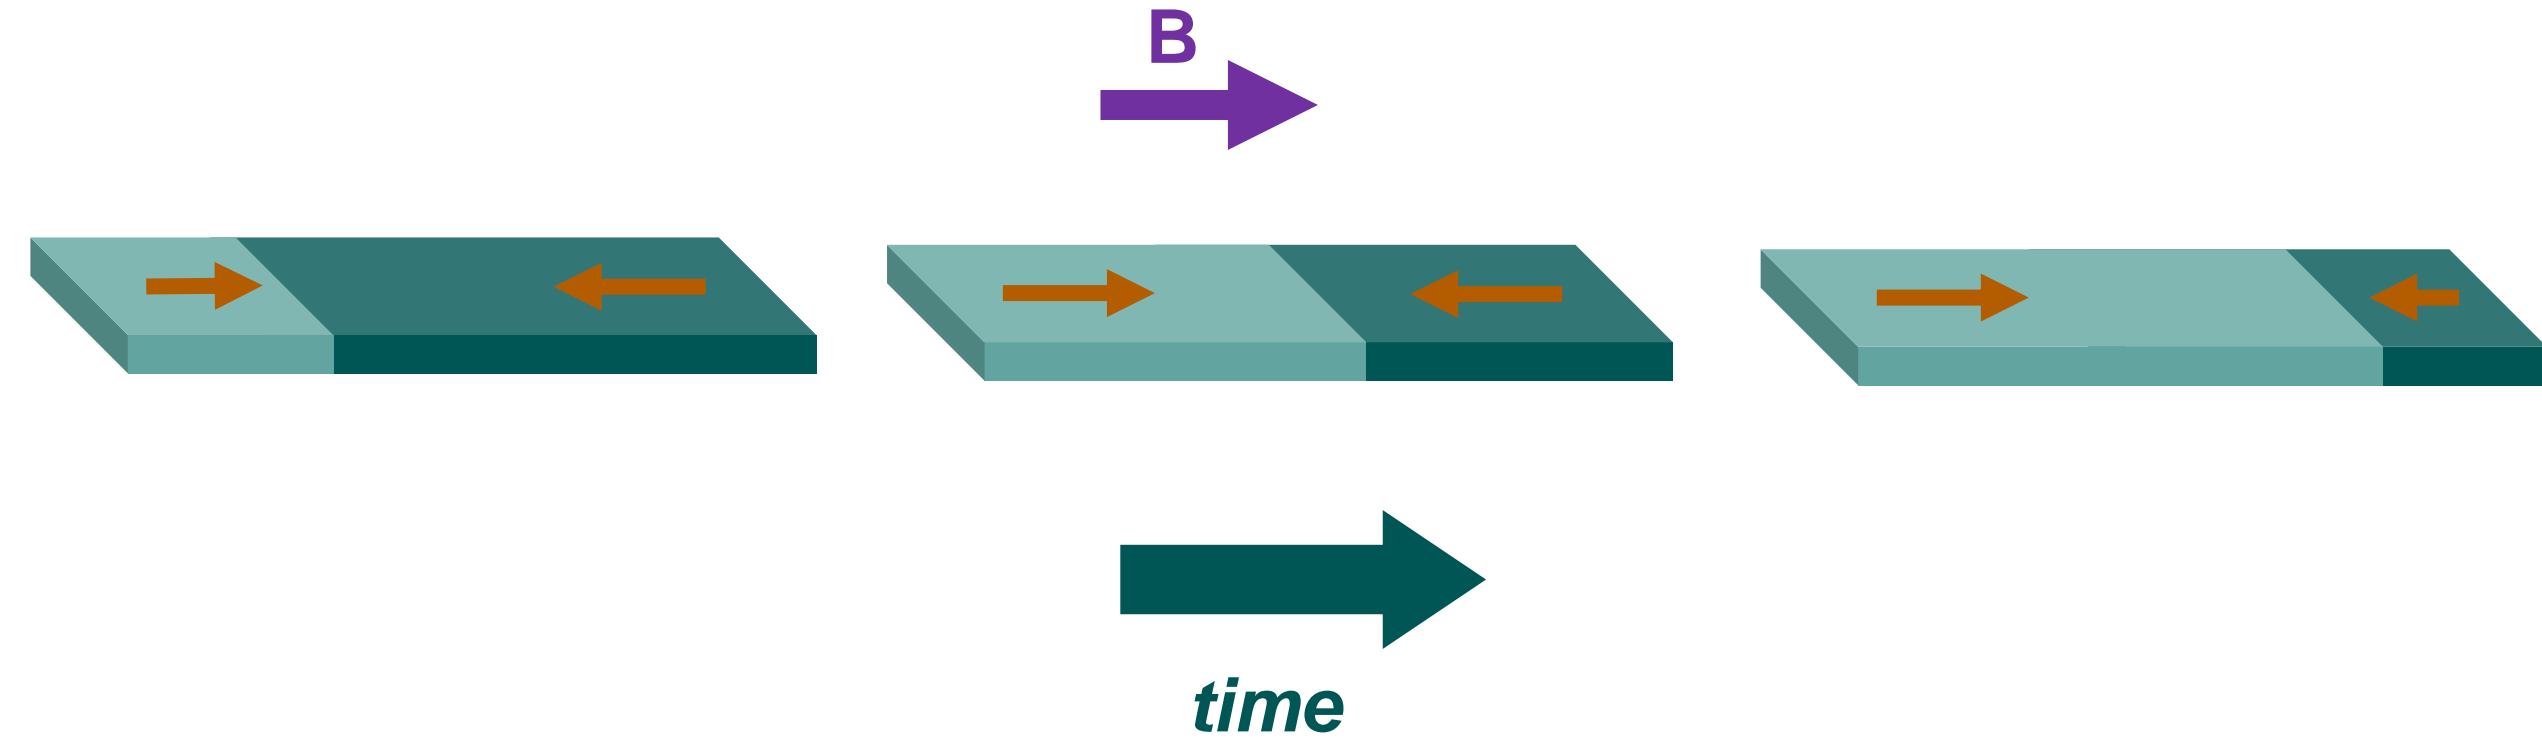

Domain walls move  
to grow domains

# DOMAIN WALL DYNAMICS

As domain wall moves, Zeeman energy decreases:

$$E = -\mu_0 M \cdot H$$

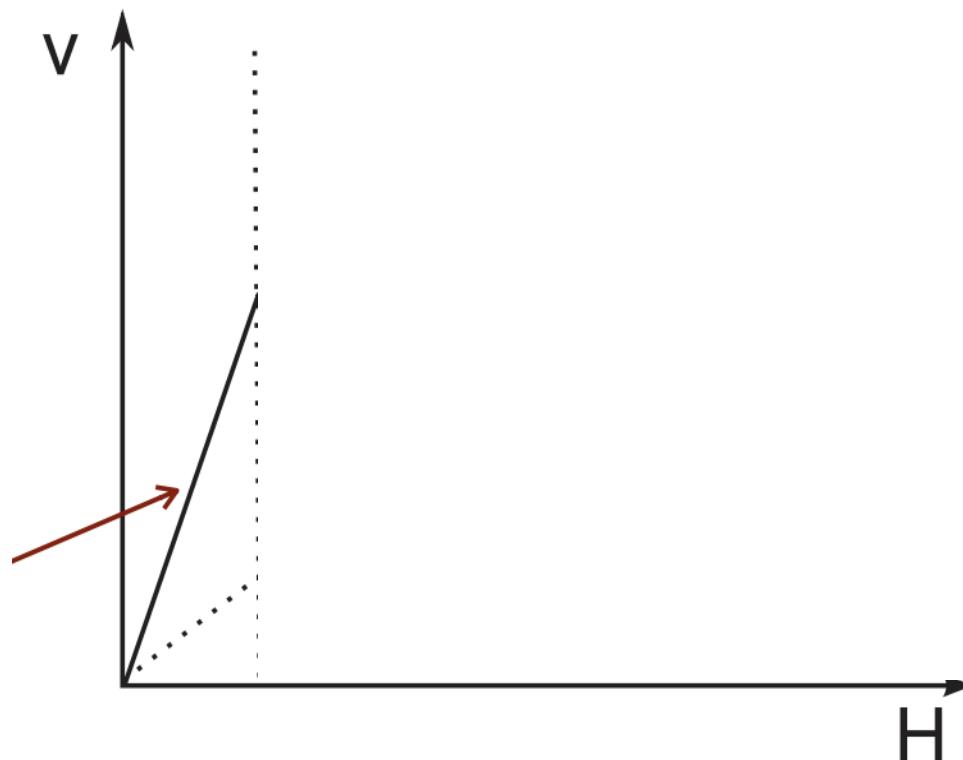

# DOMAIN WALL DYNAMICS

$$v = \frac{\gamma_0 H \lambda}{\alpha}$$

Steady state motion

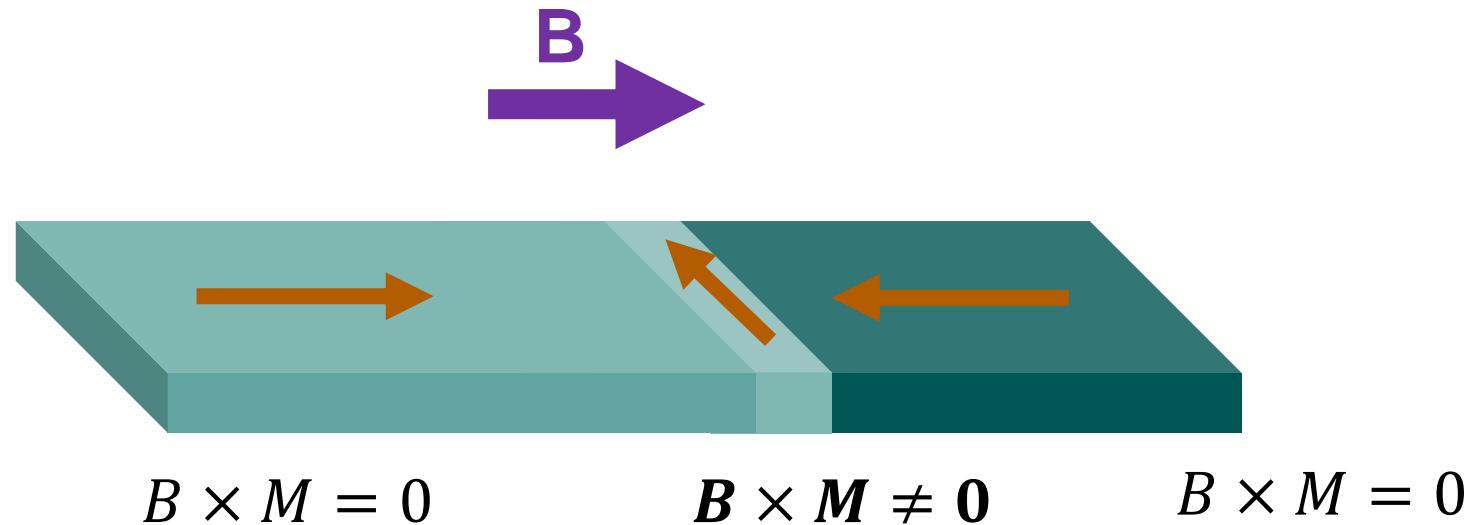

“viscous regime”

When pinning doesn't dominate

# DOMAIN WALL DYNAMICS

Wall will feel a torque – start to tilt  
For strong enough fields, the wall will start to precess!

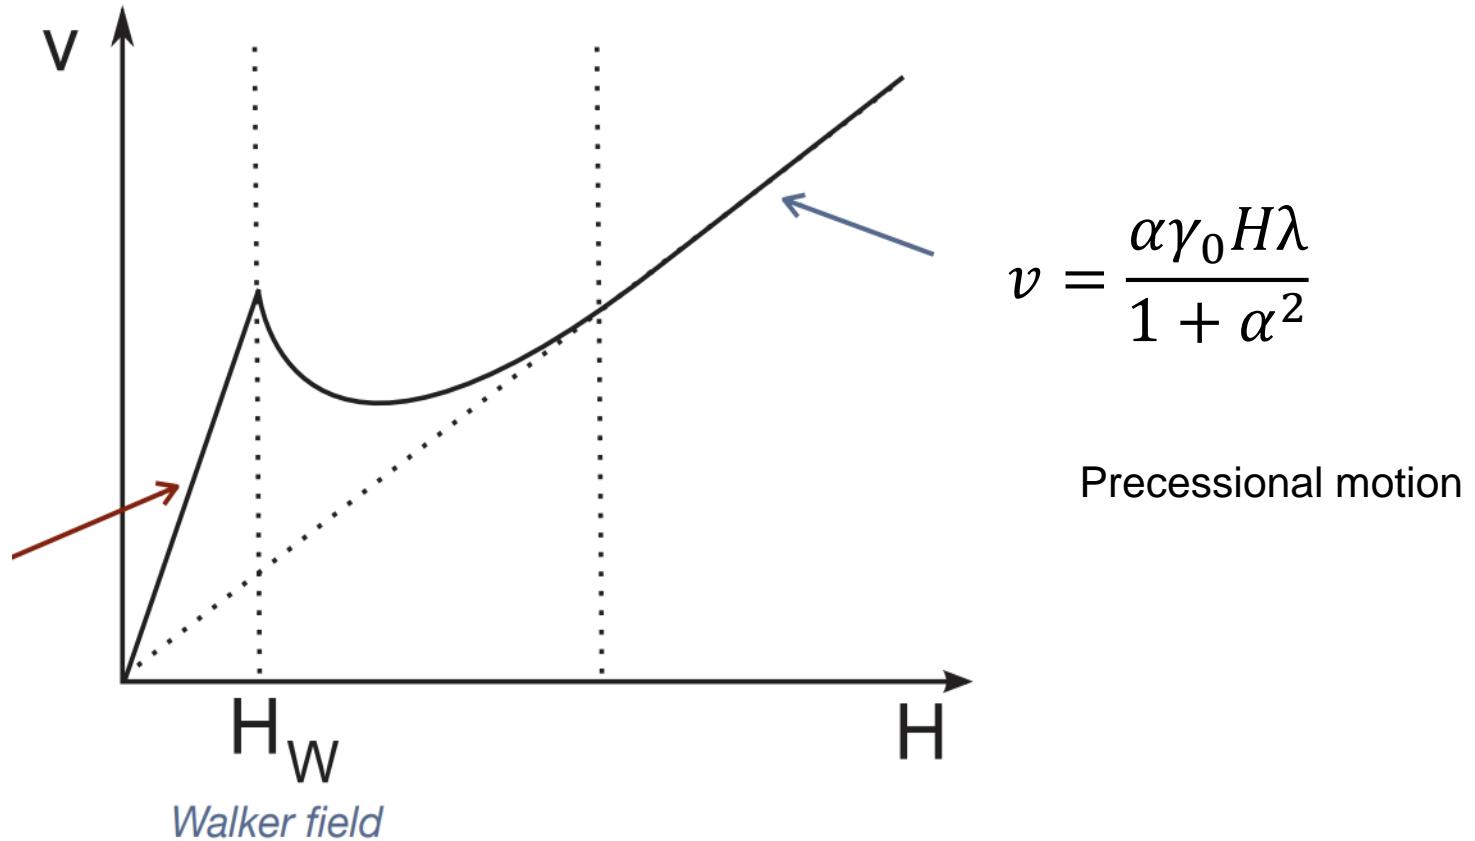

# DOMAIN WALL DYNAMICS

$$v = \frac{\gamma_0 H \lambda}{\alpha}$$

Steady state motion

“viscous regime”

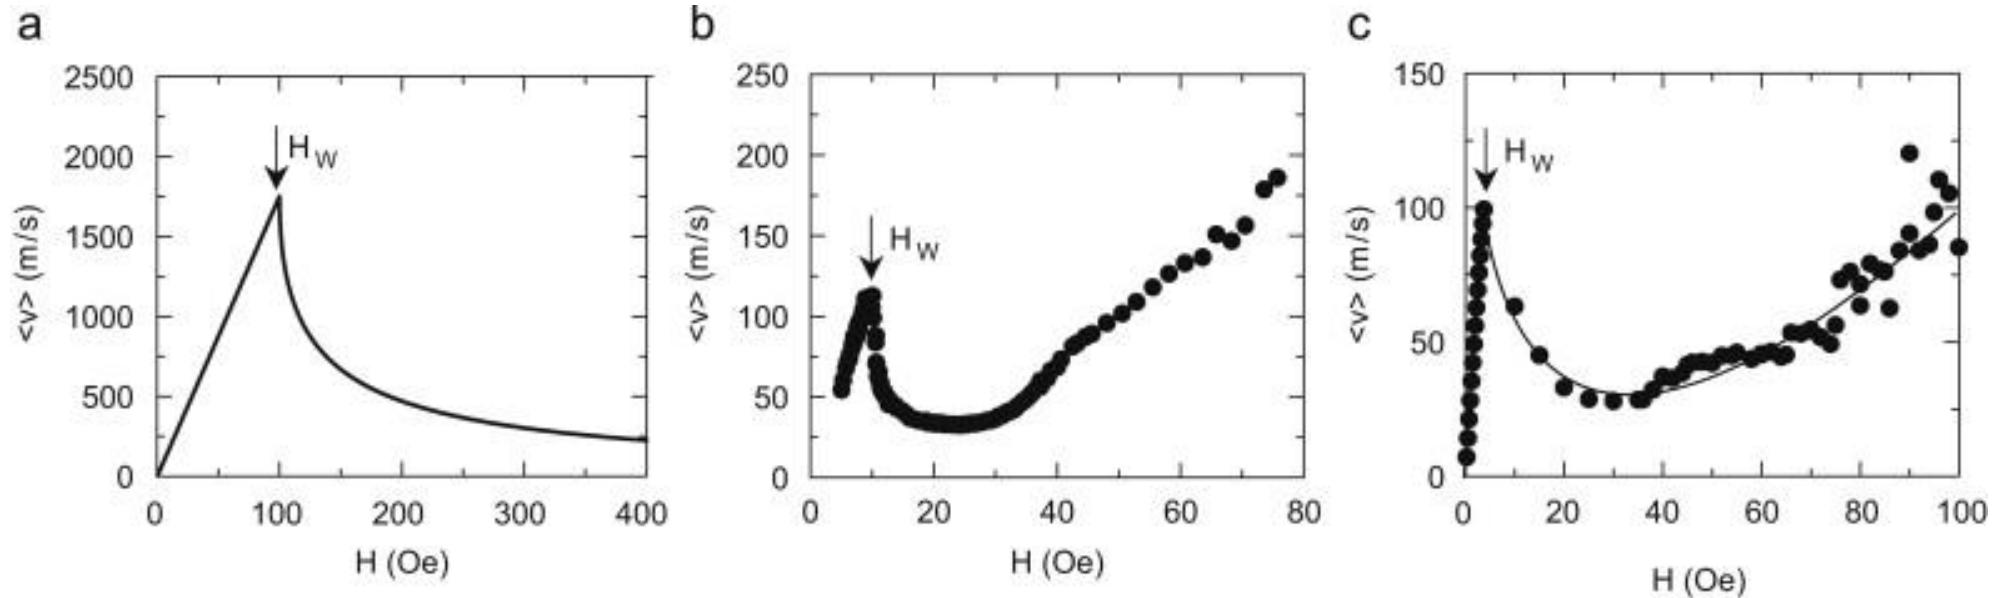

When pinning doesn't dominate

$$H_C = \frac{\alpha M_S}{2}$$

# WALKER BREAKDOWN: EXPERIMENTALLY

Experimentally confirmed in 500nm x 20 nm permalloy wire:

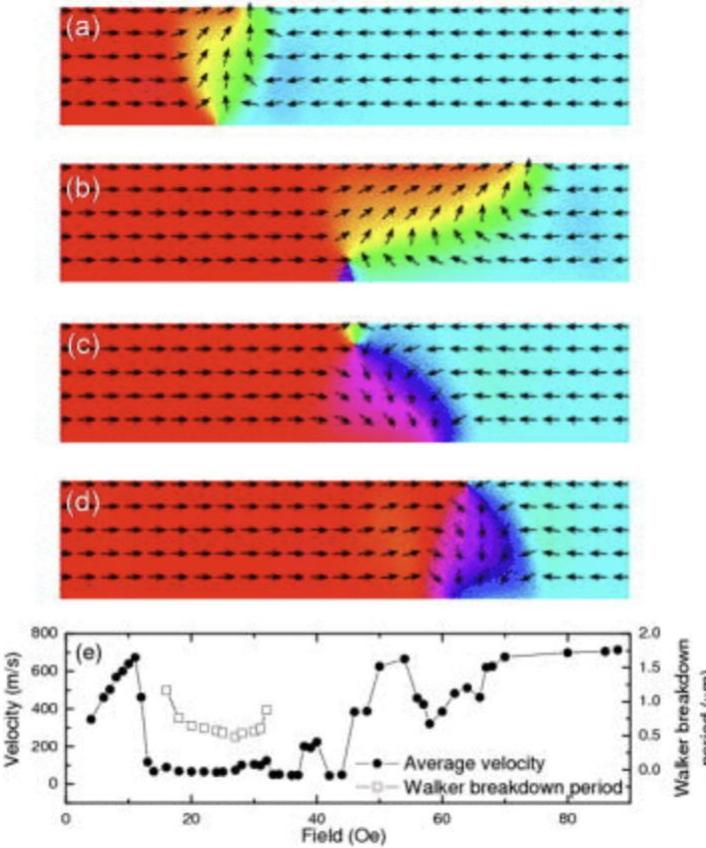

Domain wall propagated by spin-polarised current

Beach et al., JMMM 320, 1272 (2008)

# IN REAL SYSTEMS: NANOWIRES

Burn & Atkinson Appl. Phys. Lett. **102**, 242414 (2013)

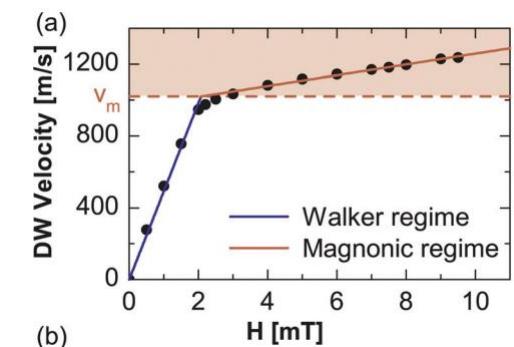

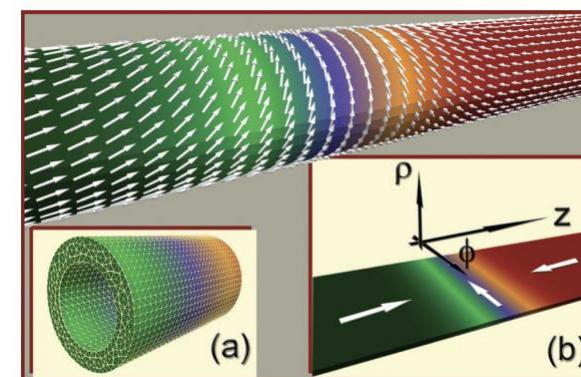

Edges play a role!

Can avoid by going to different geometries:

APPLIED PHYSICS LETTERS **99**, 122505 (2011)

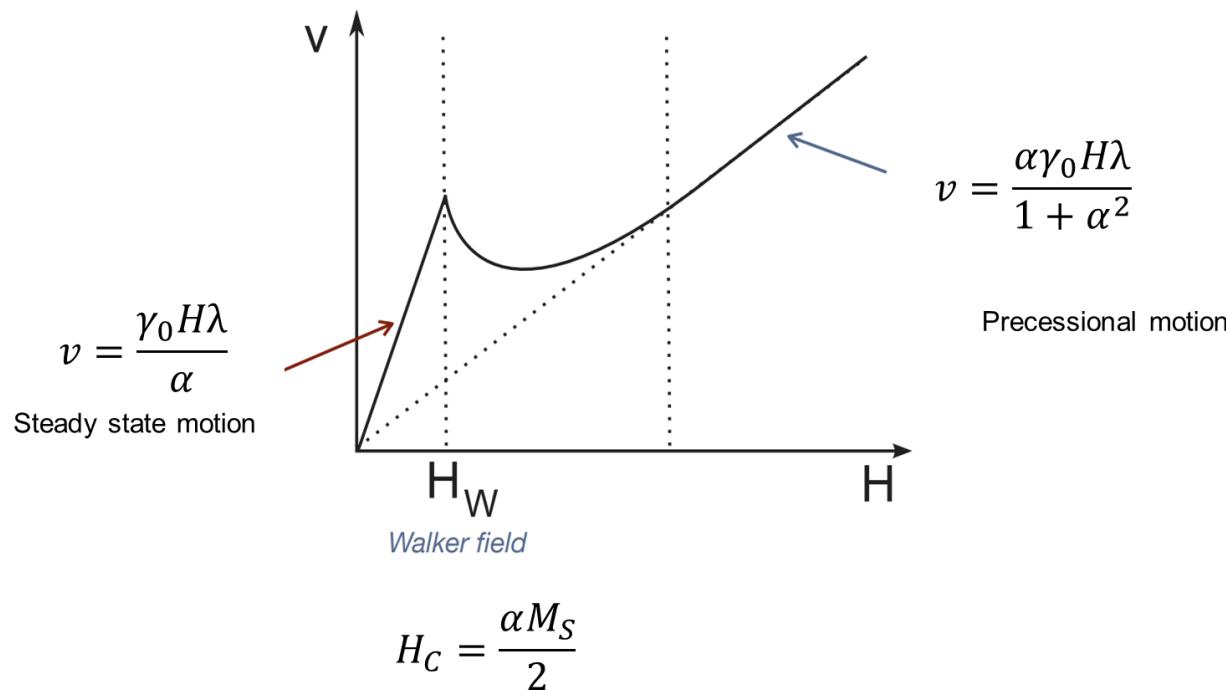

Fast domain wall dynamics in magnetic nanotubes: Suppression of Walker breakdown and Cherenkov-like spin wave emission

Ming Yan,<sup>1,a)</sup> Christian Andreas,<sup>1</sup> Attila Kákay,<sup>1</sup> Felipe García-Sánchez,<sup>1</sup> and Riccardo Hertel<sup>1,2</sup>

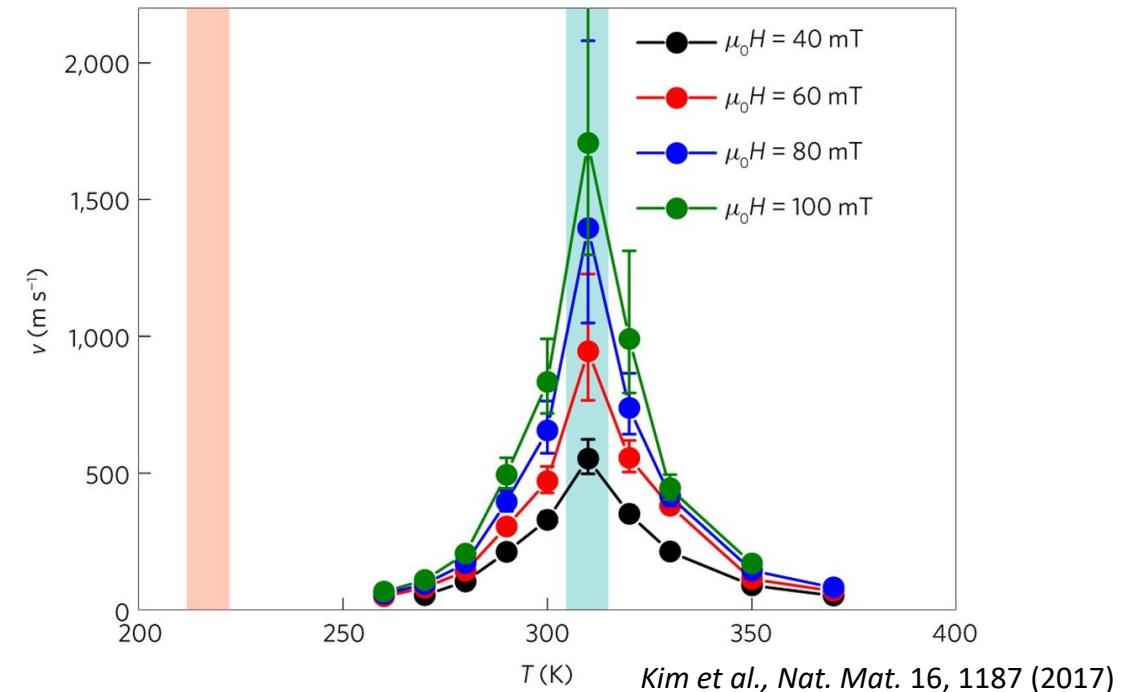

# WALKER BREAKDOWN:

**The Walker breakdown limits the maximum velocity of domain walls**

→ Ferrimagnets!

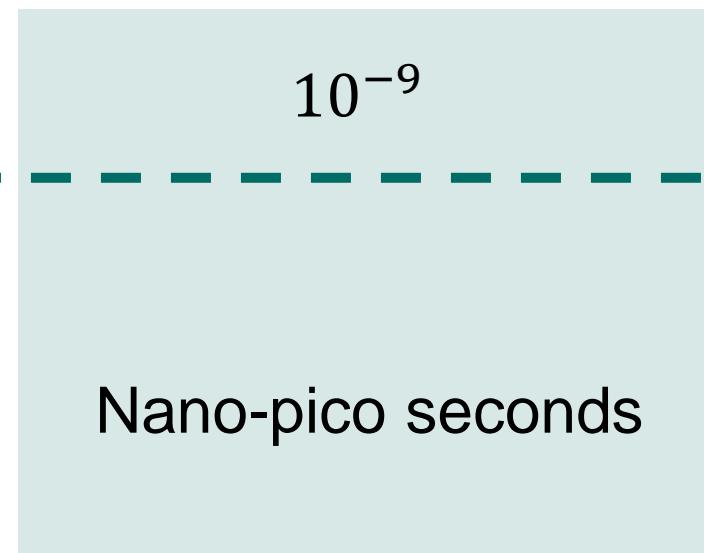

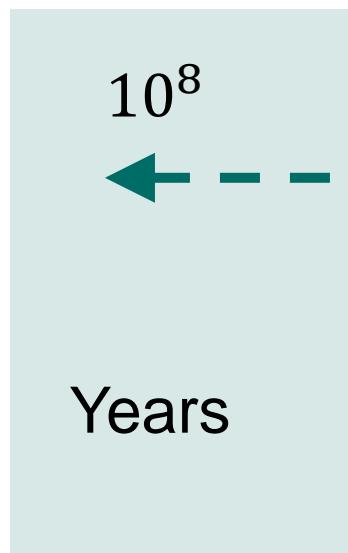

→ At compensation temperature,  $M_S \rightarrow 0$

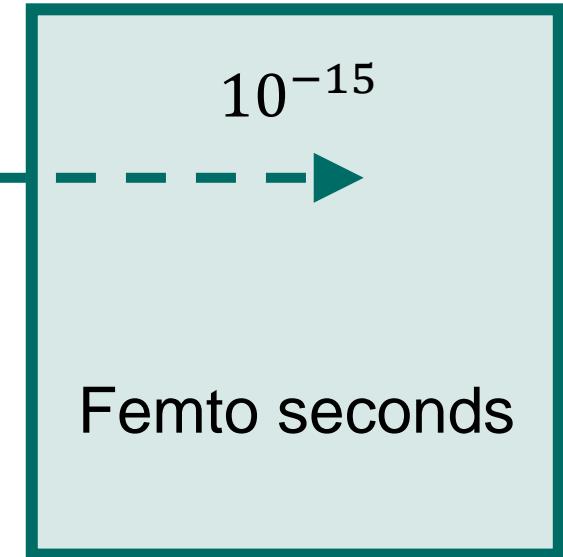

# DYNAMICS – WHAT TIME SCALES?

Slow!

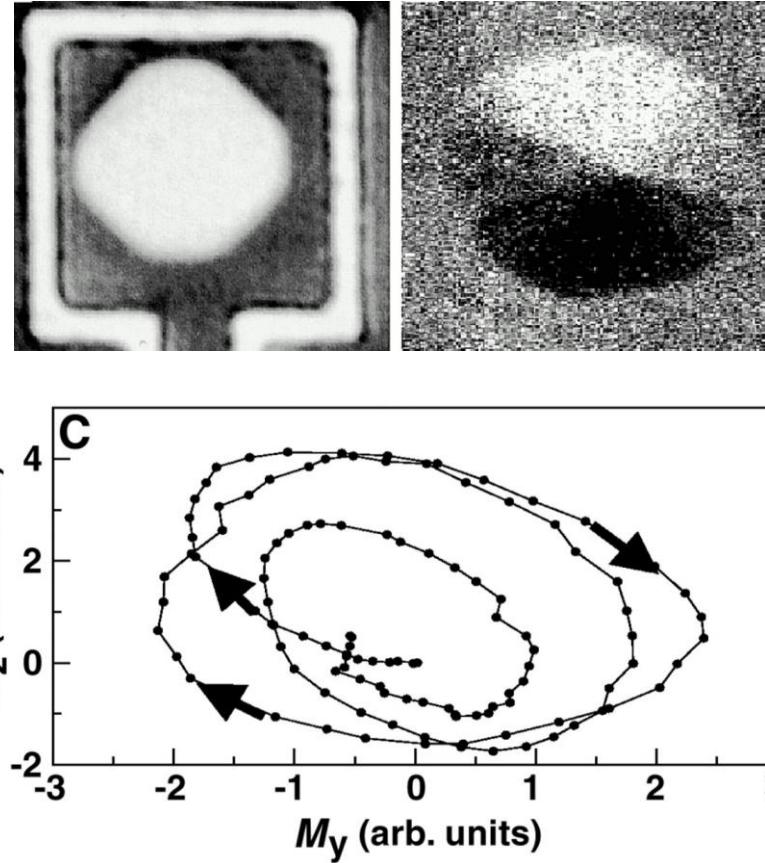

GHz - THz

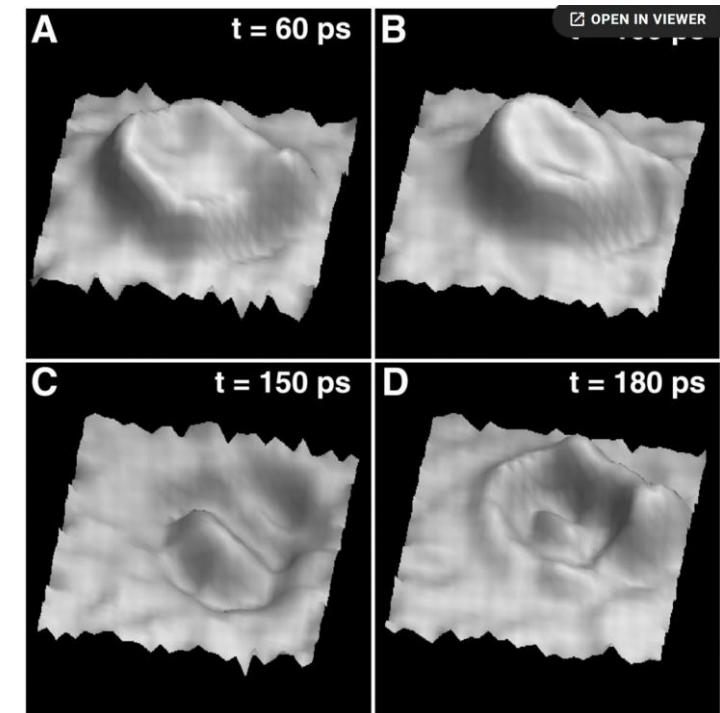

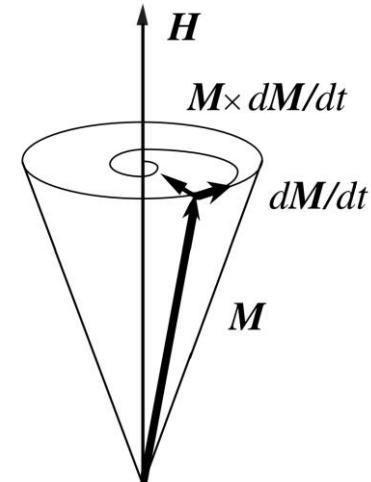

Ultrafast!

# SPIN-FLIP: HOW FAST CAN WE GO?

Acremann et al., *Science*, 290, 492 (2000)

- Time-resolved Vector MOKE
- $M_z$  field pulse
- Larmor's theorem: precessional orbit of the magnetisation
- Microscopy: get spatial resolution:

# SPIN-FLIP: HOW FAST CAN WE GO?

Does this precessional motion matter?

Yes – for devices it limits the speed!

---

## The ultimate speed of magnetic switching in granular recording media

Applied physics

## Speed limit ahead

C. H. Back and D. Pescia

---

Are there any limits to what science and technology can achieve?  
When it comes to recording data in magnetic media, the answer is yes:  
there is a natural limit to the speed at which data can be encoded.

→ Limited to ~100s picoseconds

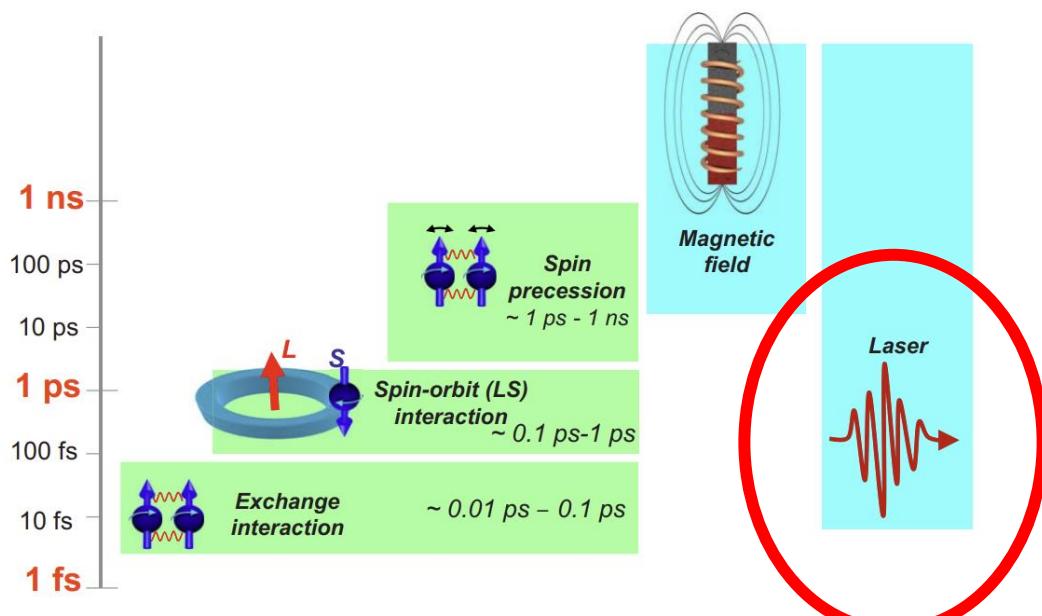

# DIFFERENT TIME SCALES:

REVIEWS OF MODERN PHYSICS, VOLUME 82, JULY–SEPTEMBER 2010

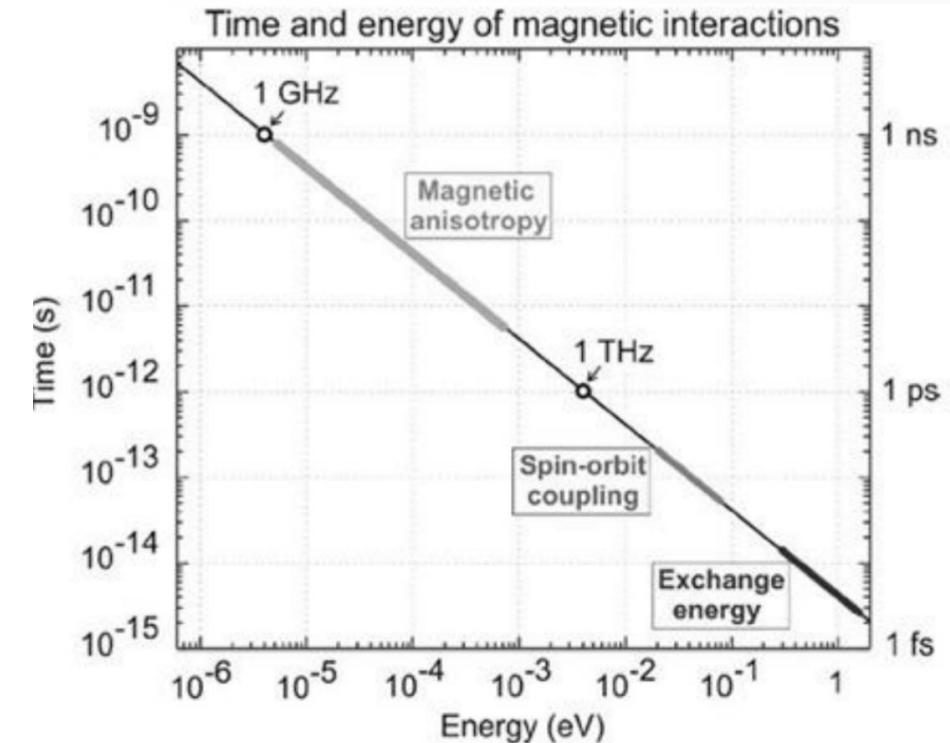

## Ultrafast optical manipulation of magnetic order

Andrei Kirilyuk,\* Alexey V. Kimel, and Theo Rasing

Radboud University Nijmegen, Institute for Molecules and Materials, Heyendaalseweg 135, 6525 AJ Nijmegen, The Netherlands

There are faster time-scales out there!

Stoehr et al., Magnetism Springer-Verlag, (2006)

# GOING ULTRAFAST

So far, we have looked at **thermal and magnetic field/ current driven dynamics**

- Indicate that it is limited to ~ns, ps.
- However, when excited by a femtosecond laser, spin dynamics can be sub-pico second!

VOLUME 76, NUMBER 22

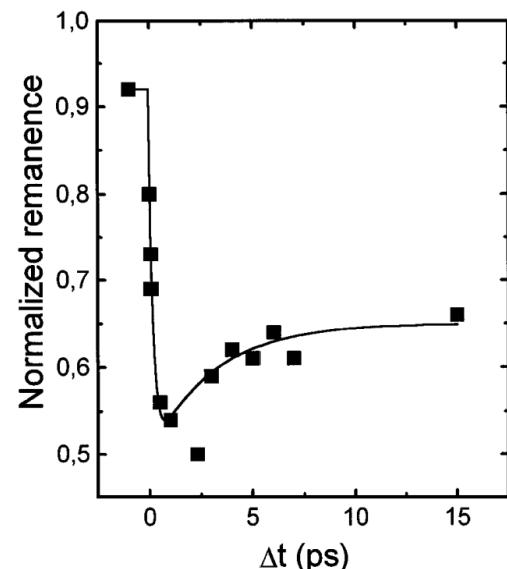

PHYSICAL REVIEW LETTERS

27 MAY 1996

## Ultrafast Spin Dynamics in Ferromagnetic Nickel

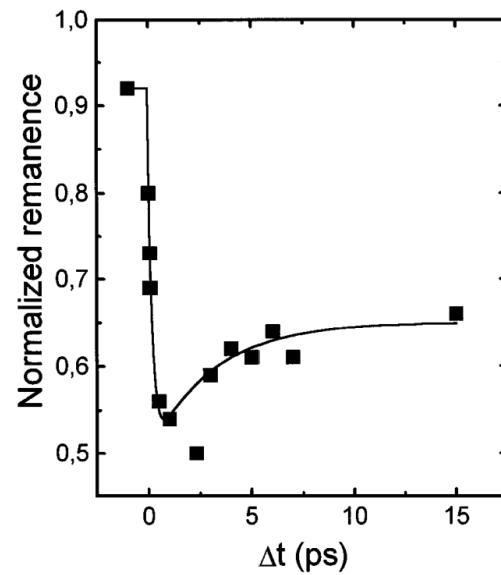

E. Beaurepaire, J.-C. Merle, A. Daunois, and J.-Y. Bigot

*Institut de Physique et Chimie des Matériaux de Strasbourg, Unité Mixte 380046 CNRS-ULP-EHICS,  
23, rue du Loess, 67037 Strasbourg Cedex, France  
(Received 17 October 1995)*

# FEMTOSECOND DYNAMICS: ULTRAFAST DEMAGNETISATION

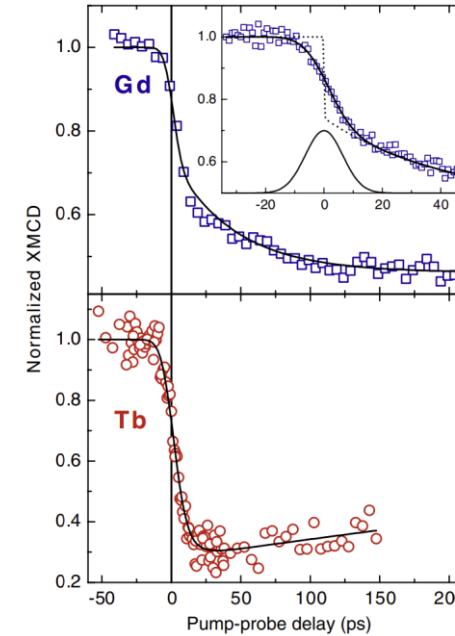

**Nickel**

- Demagnetisation in sub-ps time scale
- Recovers  $\sim$  ps

Beaurepaire et al., Phys. Rev. Lett. 76, 4250 (1996)

**Gadolinium**

- Demagnetisation in 10/100 ps timescale

Wietstruk et al. Phys. Rev. Lett. 106, 127401 (2011)

# ULTRAFAST: WHAT'S HAPPENING?

Longer time scales:

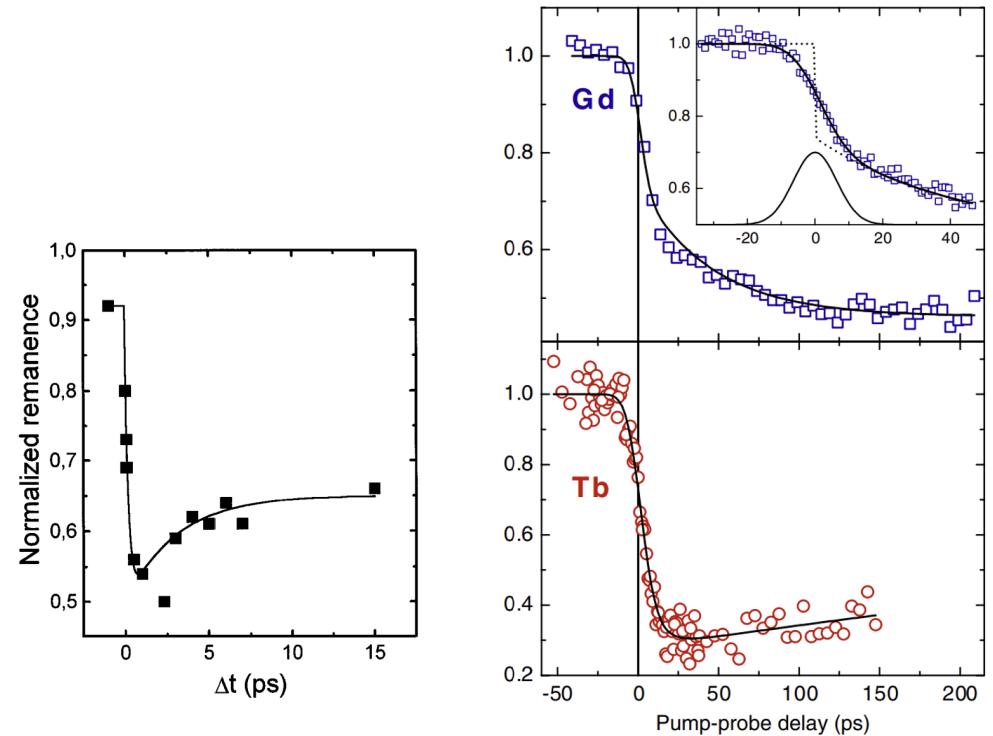

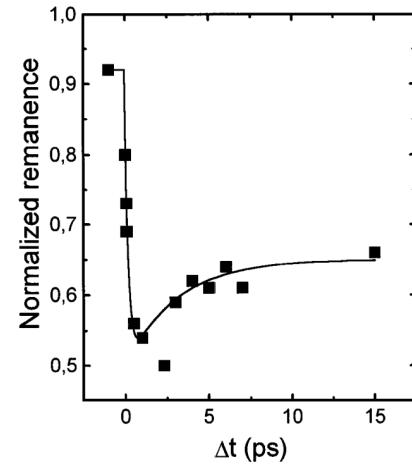

**Spin & lattice in equilibrium**

Fast time scales:

**Lattice-driven spin demagnetisation!**

**Electrons act as heat bath for spin system**

→ **Effective heating of the spins above the Curie temperature**

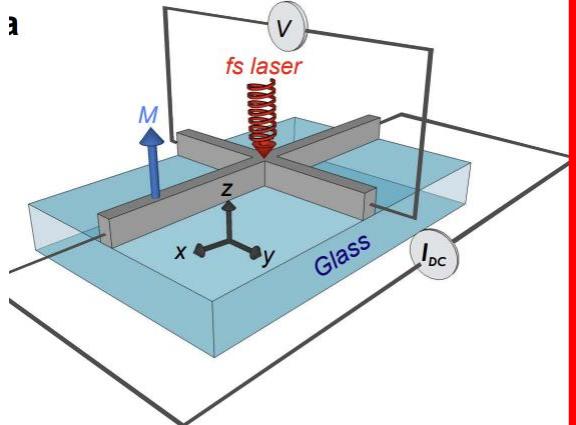

**Ni vs Gd?**

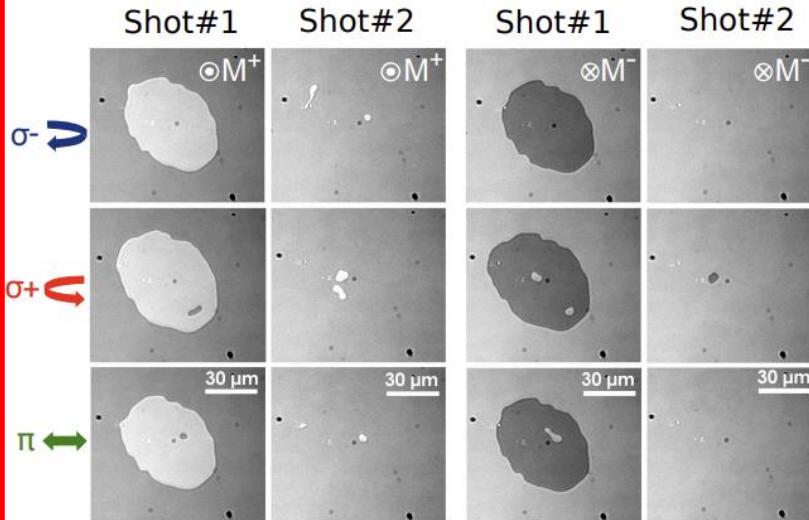

**Magnetic moment ~ Angular momentum**

**Moment of Gd larger ( $7.3$  vs  $1.26 \mu\text{B}$ )**  
**Rate of change of L ~ similar**

# ULTRAFAST DYNAMICS: SWITCHING?

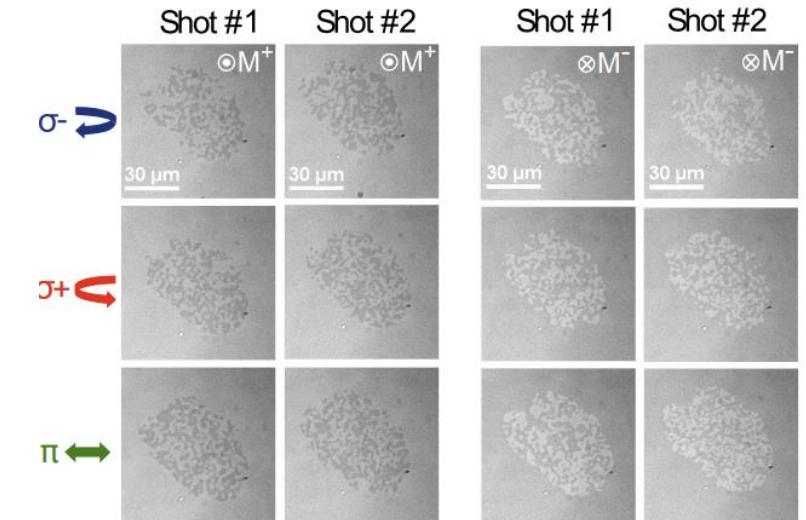

Ferrimagnetic alloy, GdFeCo

- Helicity independent, single shot switching
- Single shot: how fast?

**Fast switching!**

Ferromagnetic Co/Pt multilayers

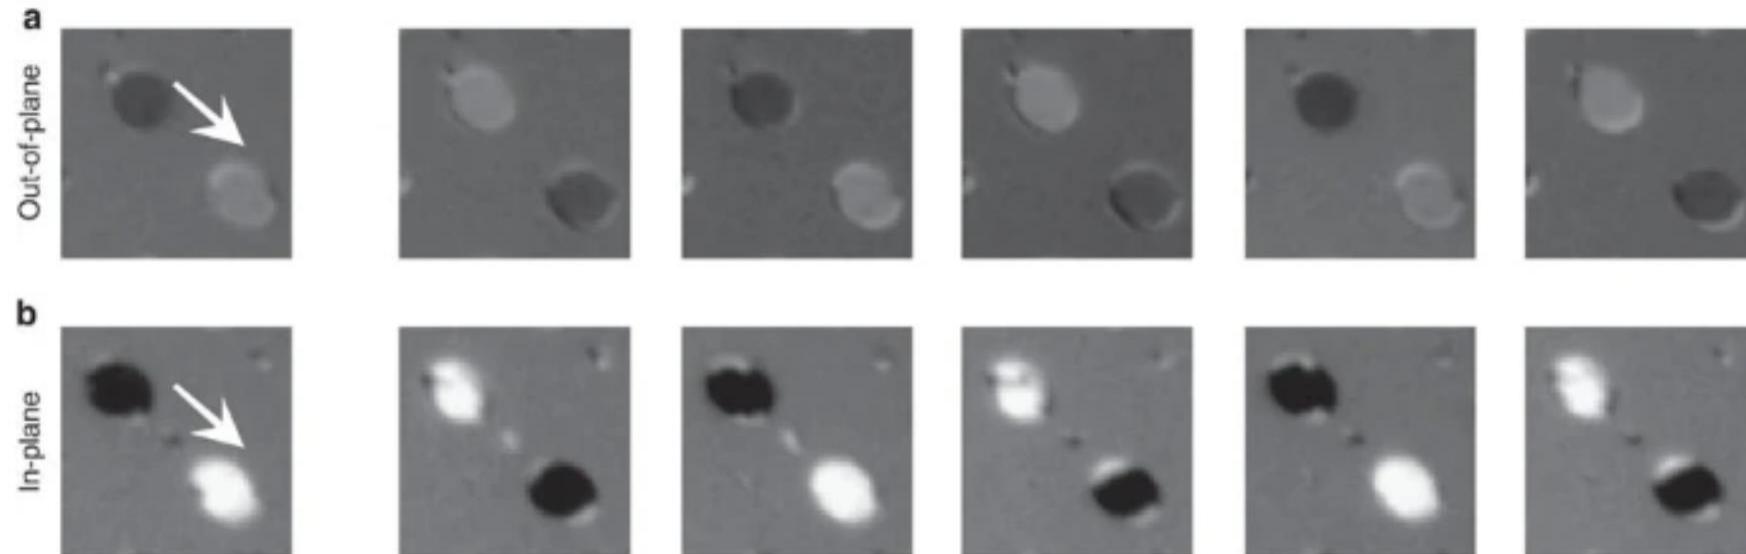

- Multi-pulse, helicity dependent optical switching
- ~ms

Ei Hadri et al, Phys. Rev. B , 94, 064412 (2016)

# ALL-OPTICAL SWITCHING
